NEW JERSEY HISTORIC BRIDGE DATA

STRUCTURE # 1100068 **CO** MERCER **OWNER** COUNTY **MILEPOINT** 0.0

NAME & FEATURE INTERSECTED HUNTER ROAD (ABANDONED) OVER MOORES CREEK **FACILITY** HUNTER ROAD (211.13)

TOWNSHIP HOPEWELL TOWNSHIP

TYPE PONY TRUSS **DESIGN** PRATT PIN CONNECTED **MATERIAL** Metal

 # SPANS 1 **LENGTH** 43 ft **WIDTH** 15.8 ft

CONSTRUCTION DT 1889 **ALTERATION DT** **SOURCE** COUNTY RECORDS

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located on Howell Farm, a living history Mercer County park that documents turn-of-the-century agrarian life. Its integrity of setting is extremely well preserved. The bridge was closed to vehicular traffic in 1983, when a crack and buckling on the top chord was discovered. The bridge presently serves as a pedestrian bridge from a parking area to the farmhouse and farm-related buildings.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Phillips / Howell Farm Historic District. 05/02/1977. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The basically unaltered 3-panel 1889 pin-connected Pratt half hip pony truss supported on ashlar abutments is individually eligible for listing in the National Register of Historic Places and is a contributing element to the National Register-listed Phillips Farm, now the Howell Farm county park, under Criteria A and C. The bridge is one of the most complete examples of its type in the county, and its significance is enhanced by the integrity of its well-preserved pastoral setting. One other Pratt half hip pony truss was identified (1100028), and both are evaluated as eligible.

INFORMATION

Bibliography:
ONJH. National Register of Historic Places File: Mercer Co.; Hopewell; Phillips Farm.
Mercer County Engineers Office. File 211.13.

Physical Description: The 10 degree skew 3-panel pin-connected half hip Pratt pony truss bridge with a plank deck survives in a good state of preservation. With the exception of a floor beam replaced in 1945 and a corresponding outrigger added, the span appears to be unaltered. End posts and the spliced top chord (cracked and buckled because of corrosion and overloading) are built-up box members, and the verticals are channels with both battens and lacing. Eye bars compose the bottom chords while the diagonal and counters in the central panel are rods with loop-forged eyes. The abutments are rusticated ashlar with some concrete repairs to the south end. The one original built-up floor beam is deeper in the middle where more strength was needed. The bridge was closed to vehicular traffic in 1983 by the county. It serves as a foot bridge from a parking area to the Phillips Farm (Howell Farm) farmhouse.

Historical and Technological Significance: Few bridges in Mercer County survive in their original setting as well as the basically unaltered pin-connected half hip Pratt pony truss on the grounds of the Phillips Farm (Howell Farm), individually listed in the National Register of Historic Places in 1977. The 127-acre farm was donated to Mercer County in 1976 by Inez Howell for use as a living history museum that preserves turn-of-the-century farm life. She was the widow of former New Jersey Senator Charles Howell who died in 1973. The couple had purchased it as their retirement home. The farm, which includes a host of well-preserved farm related buildings and a two-section homestead that dates from both the 18th and 19th centuries, is historically associated with the Phillips family which owned it from the 1730s until the 1880s. From 1920 until 1948 it was the Cromwell dairy farm.

While the single-lane 1889 pin-connected Pratt truss (located on a now abandoned section of Hunter Road that is within the National Register-listed parcel) is not rated in the nomination, it clearly falls within the period of significance of the property. The nomination states that the farm is "unchanged since the early 20th century, including the setting" of which the bridge is a major element. The bridge is one of the most complete examples of the once-common Pratt pony truss in the area. Another well-preserved half hip Pratt pony truss is located on the Groveville-Allentown Road over Doctors Creek (1100028). It is larger, wider, and has different verticals.

Boundary Description and Justification: The bridge is located well within a 172-acre National Register-listed property. The bridge is a contributing element to that historic district. The bridge and its setting are significant.

SETTING / CONTEXT The bridge is located in a low-density residential area and carries a busy 2-lane road over a small brook.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Little more than a culvert, the reinforced concrete slab span with a replacement concrete deck installed in 1945 is not historically or technologically significant. It is supported on an undistinguished earlier ashlar abutment with concrete buttressing. The lattice railing with octagonal cast posts may to date to 1915. It is known to have been in place in 1927 according to county engineers office photographs. A modern beam guard rail has been added to the bridge.

DESIGNER/PATENT KING IRON BRIDGE CO. **BUILDER** KING IRON BRIDGE CO.

SETTING / CONTEXT On a rural two-lane road, the one-lane bridge crosses a small stream. The bridge enjoys integrity of setting in a rural area dominated by working farms. It is located in the sparsely developed northwestern portion of the county east of busy NJ 31.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY One of two well-preserved King Iron Bridge Co. pin-connected Pratt thru trusses in Mercer County, the Mine Road bridge is three years later than Bear Tavern Road (1100060), but is nevertheless an important example of its type. Supported on unaltered ashlar abutments, the 5-panel bridge has few visible repairs. The floor beams may not be original. It is one of four thru truss bridges in the county and ranks as the second oldest and one of the least altered.

INFORMATION

Bibliography:
Simmons, David A. "Bridge Building on a National Scale: The King Iron Bridge and Manufacturing Company." The Journal of the Society for Industrial Archaeology. Vol. 15, No. 2, 1989.
Mercer County Engineers Office. Transfer File 230.3.

Physical Description: The seven panel half-hip pin-connected Pratt thru truss with a steel grate deck installed in 1976 has true hangers that twist 90 degrees out of phase and then pick up the end floor beams. The bearings rest on ashlar abutments. The inclined end posts and upper chord are built-up members composed of shallow channels with a face plate. The same dimension channels are used for the laced verticals. Diagonals (of bar stock with loop-forged eyes) and counters (rods) are fitted with turnbuckles for tuning the bridge, and the bottom chord is die-forged eyebars. The originality of the rolled I beam floor beams is not known, but it is believed that they are not original. They are cut back in section for the suspenders and large square nuts that do appear to be original. The floor beams are fitted with the original brackets for the lateral bracing. The portal struts have a lattice bracing, as does the sway bracing, and each end carries a King Iron Bridge and Manufacturing Co. plaque. The lateral bracing is connected to a crimped bracket that connects at the upper panel point pins. A few welded repairs to the verticals at the panel points are visible, but otherwise the bridge is very well preserved. The modern beam guide rail is attached to the verticals by bolts.

Historical and Technological Significance: The well-preserved 102'-long pin-connected thru truss by the King Iron Bridge and Manufacturing Company of Cleveland, Ohio was erected in 1885, according to its plaque, and is one of two well preserved King thru trusses from the 1880s in Mercer County. The Mine Road bridge, the longer, heavier, and newer of the two, as well as its counterpart on Bear Tavern Road (1100060), are of statewide importance as early examples of a historic bridge type. They are also examples of bridges fabricated by one of the largest and most successful late-19th century manufacturers. The two Mercer County bridges are believed to be the only documented King Iron Bridge and Manufacturing Company in the state. Technologically they reflect early metal truss bridge construction details, such as the true floor beam hangers, the lateral bracing connections, and the prong-like floor beam connectors at the verticals. The bridge is an early and very well preserved example of its type.

The King Iron Bridge and Manufacturing Company was established by Zenas King in Cleveland about 1860. Learning the bridge selling business in the 1850s as a salesman representing the Moseley Bridge Company (a patented tubular bowstring), King patented his own tubular bowsting bridge that was to be the company's chief product through the 1870s, and he successfully marketed it nationally through a network of regional representatives. He published catalogues in 1875 and 1884 as well as annual reports. As the market moved away from the light bowstring truss about 1880, he diversified his product line to include the what was becoming standard thru and pony trusses. The King company was one of the largest and most prolific bridge fabricating firms in the country yet only approximately half a dozen documented examples of the firm's work survive in New Jersey. While the company remained an active, viable concern for about a decade after the founder's death in 1892, it was not a regional force in this century.

The King Iron Bridge and Manufacturing Company, known as the King Bridge Company after 1892, represents, in addition to period engineering and technology, the manner in which iron and early steel bridges were marketed in this country. The fabricator served as both engineer and builder. That practice was to disappear with the rise of the consulting engineer and the professionally trained county engineer in the early years of this century.

SETTING / CONTEXT The well-preserved 3-span bridge, accessed by a steep descending curve, is located on a closed portion of road in a wooded setting. Some of the surrounding land is dedicated to green space by its corporate owners. The bridge was closed to vehicular traffic by the county because of constant disregard for weight limits and damage from vehicular impact. It is now a pedestrian and bicycle bridge. There are no plans to remove the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The documented and well-preserved riveted Warren pony truss is the longest of its type in the county and is one of the best preserved. It was fabricated by Berlin Construction Company of Berlin, CT, a firm that built riveted Warren trusses into the 1920s. The ashlar piers may predate the bridge, and they added to significance of the span. Warren pony trusses were the most common type of bridge in America prior to 1925, but it is not as common in New Jersey.

Darnell, Victor. Interview with Mary McCahon. 10/18/91.
Mercer County Engineer's Office.

Physical Description: The 3-span bridge is composed of three sets of riveted Warren pony trusses supported on high ashlar abutments and piers. The substructure may well be from an earlier span. The inclined end posts and top chord are built up box members of channels and plate while the diagonals (there are no verticals) are toe-in channels that are either laced or connected by battens. Connections at panel points are riveted to gusset plates. The most unusual design detail of the bridge is the square-headed bolts that serve as the floor beam hangers. The hanger bolts pass through a plate riveted to the top of the lower panel point. The rolled I-section floor beams appear to be original, but the stringers were replaced in 1930. Repair work in the 1950s included replacing "rotted" gussets and bottom chord angles in kind. The original lattice railing survives. The bridge is well preserved in both setting and design, and it serves as a pedestrian bridge.

Historical and Technological Significance: The well-preserved 3-span riveted Warren pony truss is an important example of a once-common bridge type. One of three surviving Warren pony trusses in Mercer County, the Province Line Road bridge is the longest as well as most complete of the group. It was designed and fabricated by the Berlin Construction Company of Berlin, Connecticut in 1903. The Berlin Construction Company is an offshoot of the Berlin Iron Bridge Company, which was acquired by the American Bridge Company in 1900. When Berlin Iron Bridge Company, made famous by its lenticular truss bridges, was taken over, three executives formed a new company for the purpose of fabricating and erecting structural steel. Incorporated in New Jersey in 1900 and in Connecticut in 1905, the Berlin Construction Company leased a fabricating plant in Pottsville, Pennsylvania and maintained offices in New York and Boston. Its headquarters and fabricating yard, however, remained in Berlin, and the company produced building structural steel as well as bridges. It ceased bridge fabrication by the mid-1920s. According to bridge historian Victor Darnell, Berlin Construction Company's bridge work was dominated by straight-forward riveted Warren trusses. Original plans for the bridge survive in the Mercer County Engineer's Office. The bridge was designed by the Berlin Construction Company.

The corporate history of the firm illustrates the dominant influence the American Bridge Company had on bridge fabrication at the turn-of-the-century. As first J.P. Morgan and Company and then U.S. Steel acquired 50% of the nation's fabricating capacity, new firms were established in the wake of the reorganization. Berlin Construction, still in business as the Berlin Steel Construction Company specializing in building steel, was for a time able to be a profitable small fabricator making standardized designs. While not technologically innovative, the Province Line Road bridge stands as not only a well-preserved example of a small post-American Bridge Company fabricator but also a record of the history of technology at the turn of the century. The riveted Warren pony truss, according to J.A.L. Waddell, was the most common bridge type in the country prior to 1925.

Boundary Description and Justification: The bridge is evaluated as individually significant, and the boundary is thus limited to the substructure and superstructure itself. While the wooded setting contributes to the integrity of setting, the acreage does not appear to have significant historical value. The road itself once served as the boundary between the east and west Jersey provinces, but it has lost its integrity due to modern development.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 07/09/90, Letter 03/12/01.

SUMMARY Moved to its present location in 1924, the riveted Warren pony truss appears to date to ca. 1905. It is composed of angles, set back-to-back with spacers. The top chord is braced at the panel points with a laced outrigger. There are numerous welded repairs and strengthening. The trusses were too short for the crossing, so a stringer approach span and concrete pier were added. The ashlar abutments date to 1869. The undocumented span is individually eligible for listing in the National Register of Historic Places under Criterion C.

INFOR MATION

Bibliography:
Mercer County Engineer's Office. Bridge Transfer File # 670.4.

PHYSICAL DESCRIPTION The 78'-long 7-panel riveted Warren pony truss was relocated to this site in 1924. The south end of the trusses bears on a deteriorating ashlar abutment built in 1868, according to the date stone. Because the trusses were too short for the crossing, a concrete pier and rolled stringer approach span were built in 1924 to accommodate using the truss lines at this location. Both spans have a plank deck. The truss members, including the top and lower chords, are composed of angles riveted back-to-back. The inclined end posts and diagonals have washers or spacers at the rivets. The floor beams are suspended from U-bolt hangers that rest on a two-piece saddle fitted beneath what remains of the gusset plate at the panel point. The floor beams, with punched holes in the top flanges and in some webs, are hung from two U hangers with hex-headed bolts. All other connections are riveted, including the original laced knee braces with square-headed bolts. Portions of the original/early lattice railing survive on the truss spans, but it has been replaced elsewhere by modern beam guide rail barriers. There are numerous small welded repairs and strengthening to the lower portion of the trusses, and they also have impact damage.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE The present 2-span bridge over Crosswicks Creek, erected in 1924 as an intercounty (Mercer and Burlington) project, is at least the second bridge at the crossing. It utilizes the handsome but deteriorated random ashlar abutments that date to 1868. The abutments are early, complete, and documented, making them a noteworthy feature of the crossing.

The date of construction and fabricator of the riveted Warren trusses is not known. They date stylistically to ca. 1905, and they exhibit no distinctive or innovative details. The trusses were moved to this site in 1924. Since they were too short for the crossing, a new concrete pier and stringer approach span were added to the north side. The trusses are not without numerous welded patches installed as repairs or strengthening. Physical evidence suggests that the flooring system has been modified, probably when the trusses were moved. The rolled I-section floor beams have punched holes in the top flanges, and some have similar holes in the web suggesting that they are salvaged material. A similar detail of hung floor beams on otherwise all rivet-connected truss bridge is the 1904 pony truss bridge at Cedar Lane in Burlington County (03D3760). The floor beam hangers are original on that bridge making it a more complete and significant example of the detail.

The laced outriggers appear to be original. They are found on some other Warren pony truss bridges in the state, so this in not a rare example of the detail.

The undocumented span is one of three riveted Warren pony truss spans in Mercer County. It is not as complete as the 3-span 1903 Berlin Construction Company bridge on Province Line Road (1105302). Its setting, with a modern residential subdivision at to the northwest, is also not as well preserved as the Province Line Road span. The fact that is was moved is also not unusual as Mercer County was frequently moving serviceable trusses during the 1920s. A better documented example of a moved truss within the county is the Groveville-Allentown Road span over Doctors Creek (1100028). What is unusual about the Iron Bridge Road span is the hanging of the floor beams on an otherwise all riveted bridge, but that detail is believed to be a modification rather than the original arrangement. The undocumented bridge is a representative example of a common truss type and design that appears to be too altered to retain its integrity of design.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The original shallow built-up plate girder bridge on concrete abutments was widened with encased stringers on the east side in 1958. When the pony truss at the crossing collapsed in 1920, the quickest replacement span was a pair of girders fabricated by Newton Bugbee & Co. of Trenton. According to county records, rolled I beams would take too long to be made. That is why the bridge is a girder instead of a stringer. It is not historically or technically significant.

SETTING / CONTEXT The bridge and viaduct carry the D & R Canal Feeder and NJ 29, the historic river road, over Jacobs Creek at its confluence with the Delaware River. It is contiguous to and an integral part of the Somerset Rolling Mill and the canal r-o-w, both National Register-listed properties. The bridge is preserved in its original setting and is an important element in the historic character of the two National Register resources.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Listed. Somerset Rolling Mill Historic District, 11/19/74; D&R Canal. 5/11/73. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The composite arch bridge/viaduct incorporates a stone arch reportedly built ca. 1832 as part of the construction of the D & R Canal Feeder. The original arch has been widened by concrete additions on both sides, but it is still visible from the underside. Contiguous to two National Register-listed properties, the structure is not cited as a contributing element in either nomination. It is historically significant to both listings and should be rated contributing despite the 1940 alterations.

INFOR MATION

Bibliography:
1875 Beers Atlas Map: Mercer County.
Office of New Jersey Heritage: Mercer County: Somerset Rolling Mills National Register Nomination, 1974.
Mercer Co. Engineers Office. Transfer File 214.3.

Physical Description: The arch bridge/aqueduct that carries NJ 29, the D & R Canal Feeder, and the right-of-way of the former Bel-Del Railroad over Jacobs Creek was originally built 1832-1824 as a barrel-shaped stone arch finished with gauged ring stones. The structure has been widened with concrete extensions on both sides. When the concrete extension was added to the downstream side is not documented, but it appears to date to ca. 1910. A 15' reinforced concrete extension to the upstream side in 1941. The spandrel wall of the extension has been scored. A perpendicular wing wall on the upstream side survives in original condition. The entire structure was gunited in 1941. The earthen embankment above the original level of the bridge illustrates how much the historic 18th-century road level has been raised. A modern beam guard railing has been installed at the road grade.

Historical and Technological Significance: The present arch bridge/aqueduct incorporates a stone arch built as part of the Delaware & Raritan Canal Feeder development in the early 1830s. 1832 is the generally accepted date of construction for the structure. It is located on the historic river road north from Trenton and adjacent to two National Register-listed properties; the Delaware & Raritan Canal right-of-way and the Somerset Rolling Mill. Although the 1974 Somerset Rolling Mill nomination includes only the house and mill, the bridge that crosses Jacobs Creek, power source for the mill, is an integral part of the well-preserved site, both visually and historically, and should be considered a contributing resource. It also carries the Delaware & Raritan Canal Feeder over the creek. The right-of-way of the canal feeder is also listed in the National Register, but the nomination says nothing about structures such as this viaduct.

The structure is one of two similar stone arch bridge/aqueducts in Mercer County between Trenton and Lambertville. The other structure, a 2-span stone arch at Moore's Station (1110152), is in a more complete state of preservation. The Jacobs Creek structure has been extended on both sides. When the concrete extension was added to the downstream side was not documented in the records of the Mercer County Engineer, but 1940 photographs show that it was in deteriorated condition by that date. A 15' extension of reinforced concrete was added to the upstream side in 1940 as a means of preventing collapse of the badly deteriorated upstream portion of the original stone arch. It also accommodated a widening of NJ 29.

The Jacobs Creek aqueduct is significant because of its setting and association with recognized historic resources (criterion A). The canal feeder, which runs from Raven Rock to the north into Trenton and connects with the main canal, was completed in 1834. It was an important route for coal passing from the mines in Pennsylvania to the industries in Trenton and beyond. The area at the confluence of Jacobs Creek and the Delaware River, known as Somerset Junction, was an early mill site. Jonathan T. Crowley bought the grist mill located there in 1841 and enlarged it. The mill flourished through the rest of the 19th century as did the entire area. Located on the railroad line between Ewing and Hopewell, it was the junction of the short-lived Mercer and Somerset Railroad with the Camden & Amboy's Belvidere-Delaware line. The Mercer & Somerset Railroad was a subsidiary of the Camden & Amboy started in 1870 and completed to New Brunswick in 1874. The rail line was on the south side of the creek.

The old River Road, a significant 19th-century thoroughfare, has become the area's scenic highway. In 1912 the state assembly authorized construction of a 111-mile riverside route from Trenton to Port Jervis, New York, in an effort to redistribute the population of the state from the eastern portion to the Delaware Valley. The Delaware Drive Bill in 1929 provided more funds for work on the road which continued through the 1960s. The state took over the road in 1945. The section at Somerset Junction was completed in 1924.

SETTING / CONTEXT Located well below grade, the bridge that carries scenic NJ 29 over Moores Creek near its confluence with the Delaware River is not visible from the road. It is visible from the D & R Canal Feeder right-of-way, now a park, located immediately west of the bridge and highway. Elements of an abandoned railroad trestle bridge are in the adjacent park. The setting is wooded.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stone arch bridge (later gunite) dates to the construction of the D & R Canal, and as such it ranks as one of the few surviving original canal-related bridges. It is one of two stone arch bridges on NJ 29 (the historic river road), and it is the better preserved of the two. The bridge was widened in kind in 1917 when NJ 29 was improved to its present width. The gunite coating was added in 1933. The value of the bridge is for its associative significance with the D & R Canal Feeder.

INFOR MATION

Bibliography:
Trenton Public Library. Trentoniana Collection. Vertical File: Roads.
Mercer Co. Engineers Office. Transfer File 211.1.

Physical Description: The 2-span stone barrel arch bridge/aqueduct has splayed wing walls and a high road embankment. It has been widened at least twice, but the 1933 gunite coating hides evidence of the modification. The original stone construction is visible inside the arches and where the gunite coating has spalled. A bullnose cutwater has been added to the upstream side, and a high embankment has been built up on the original deck to accommodate the raising of the road grade.

Historical and Technological Significance: The stone arch bridge/aqueduct was constructed ca. 1832-1834 as part of the original development of the Delaware & Raritan Canal Feeder, one of the important transportation routes in the region. The D & R Canal Feeder, which brought soft coal from rich fields of eastern Pennsylvania to the industrialized regions of Trenton and beyond, was completed between 1832 and 1834. Its right-of-way, which was listed in the National Register of Historic Places in 1973. Since the aqueduct is an original canal structure, and it actually carries the historic waterway, it is evaluated as a contributing resource (criteria A, C).

In addition to the structure's association with the canal feeder, it is also an integral part of the old river road, an important 19th century thoroughfare. The New Jersey legislature designed NJ 29 as "Delaware Drive" in 1912. The purpose of the road was to encourage redistribution of population from the congested northeastern part of the state to the Delaware Valley by providing good transportation. The road was improved over the next fifty years, and it was taken over as a state route in 1945. This arch was extended on the upstream side in 1917 to accommodate the upgrading of the road. When the downstream side was extended is not known. That work would have been done by the Pennsylvania Railroad, owner of the canal feeder and railroad. The entire span was gunited in 1933. Despite the 20th-century alterations to aqueduct, it is of great enough historical significance to be evaluated as an eligible resource (criterion A).

The stone arch is one of two known mid-19th century bridges on the old highway in Mercer County and it is the largest. As such it is a significant remnant of the historical development of an important transportation corridors that contributed markedly to the industrial and physical growth of Trenton and Lambertville. It engineering significance is derived in part from demonstrating how the crossing of the canal, a controlled, manmade feature, and the natural stream were separated.

Boundary Description and Justification: The span is evaluated as significant for historical and technological reasons. Thus the span as well as its setting as part of the canal feeder and the historic river road are all contributing factors to its significance. The boundary includes the entire width of the structure and the area on the downstream portion that is part of the National Register-listed Delaware and Raritan Canal district.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge located at the north end of Hightstown's business district on the main street (NJ 33). It crosses a dammed stream that created a large mill pond (Peddie Lake) on the east side. The area around the bridge on both sides of NJ 33 is now an open park. Tall ashlar piers from a 19th-century railroad bridge (superstructure removed) are located on the west side of NJ 33 in full sight of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The low rise 4-span rubble-coursed stone arch bridge with a composite railing dates to at least 1907 (county records), and it contributes to the historic character of Hightstown. Each arch has a steel liner added in 1981 when the bridge was rehabilitated. The bridge and mill pond to its east are important remnant of the area's industrial heritage. A large water- and steam-powered flour and cereal mill stood east of the bridge until ca. 1920. The bridge is notable for historic associations.

INFORMATION

Bibliography;
Sanborn Insurance Maps 1885-1925.
Woodward & Hageman. Histories of Burlington and Mercer Counties. Everts & Peck, 1889.

Physical Description: Located below (west) of the dam that creates a long winding mill pond that separates the northeast corner of town from the rest of the Borough of Hightstown, the 75'-long bridge masonry bridge is composed of four small elliptical arches with ring stones and rubble-coursed spandrel walls. Modern steel liners have been installed in each arch in 1981, but the original configuration of the bridge remains the same. Probably dating to the 19th century, the rubble-coursed bridge has been repointed with modern Portland cement. The date of the composite pipe railing with stone posts is not known. No original/early plans or drawings of the bridge have been located.

Historical and Technological Significance: The undocumented 4-span stone arch bridge is locally significant for its historical association with the industrial development of the borough of Hightstown. The east side of the bridge was the location of water-powered mills dating to the mid-18th century. While no plans or drawings of the bridge were located in state or county records, local histories suggest that the stone arches were in place by 1875, and that a grist mill (non-extant) was standing at its northeast corner. In 1875 it was a flour mill, and a saw mill was located on the southern bank. G.W. Norton's grist and rolling mill, established in 1876 as the successor to William R. Norton's mill, was located in the buildings on both sides of the pond by 1890. The water and steam-powered business expanded into a large cereal rolling mill that was active through the first decade of this century. By 1916 it had changed ownership and was known as the Gross Brothers Cereal Roller Mills. All buildings disappeared by 1925, and it is assumed that they were destroyed by fire. Today the site is a public park with the bridge, dam and mill pond as its focal points.

The 1907 date of construction assigned by Mercer County is unsubstantiated. It appears that the bridge was constructed prior to 1907, which may be a date of rebuilding or rehabilitation. The crossing itself dates to the 18th century.

Boundary Description and Justification: The bridge is evaluated as individually significant. The buildings that provided its historic setting have been lost. The boundary is thus limited to the bridge itself.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER** UNKNOWN

SETTING / CONTEXT The well-detailed encased stringer bridge built across 2 tracks is located in a rural, wooded section of the county south of Pennington center. No significant structures or sites are near the bridge, and the surrounding area is dominated by 20th-century residential development.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The custom-detailed 3-span encased stringer bridge designed by NJ State Highway Department Bridge Division is representative of their work with faience tile decoration and identification at the end posts. Its structural type is common for the period. The span is similar to other railroad overpasses in the state. The bridge is neither historically nor technologically distinguished.

INFOR MATION

Bibliography:
NJDOT File: Mercer 1119150.

Physical Description: The 3-span concrete-encased steel stringer bridge is supported by concrete abutments and columns with struts and crash walls. It carries a 2-lane plus shoulder state highway over one active track of the former Reading line that is now used by Conrail. The most distinctive feature of the span is the detailing of the balustrade/parapet. The approach spans have a well-proportioned arcaded concrete balustrade with end plaques while the high center parapet is finished with flat panels with filled corners and faience tile decoration on the end posts or piers. The transition from the balustrades to the parapet is filled with a paneled console. There is loss due to deterioration of the coping.

Historical and Technological Significance: The encased steel stringer bridge was designed by the New Jersey Department of Transportation Division of Bridges in 1927, but it was not built until 1934. It is a good but not unusual example of the nicely detailed steel stringer bridges that are representative of the work of the State Highway Department Bridge Division in the late 1920s and 1930s. It is distinguished by the use of faience tile decoration, a favorite motif of Arthur Lichtenberg, head of the division's architectural section. Such ornament is reasonably common on bridges on major routes in the central part of the state, and similarly detailed overpasses are found in Middlesex County. While it is not known which producer supplied the green tone tiles used on this span, it is probable that they were made in Trenton, a national center of faience tile as well as other ceramic products. The plans specify that whatever tile is used be equivalent "to that manufactured by Mueller Mosaic Co, Trenton, N.J." Other faience tile decoration found around the state includes the state seal and mosaics with nautical themes.

The encased steel stringer bridge is the most common pre-World War II bridge type in New Jersey. Favored for its economy and ease of erection, it came to dominate the state's highways and byways in the decades between the world wars, the period of greatest road improvement in New Jersey. The type as well as the encasing with concrete were promoted by Morris Goodkind (1888-1968), Chief Bridge Engineer from 1925 until 1955.

This bridge is nicely detailed, but it is not so unusual or of such a quality that it merits individual recognition. Other spans with faience tile decoration, like 1810170 and 1209155 are more significant based on type and overall detailing. This bridge is a representative example of the high-quality designs that characterize the work of the division in the decades before World War II.

SETTING / CONTEXT The stone bridge is located on the historic right of way of the Kings Highway, the main 18th-century road between New York and Philadelphia. On the southwest edge of Princeton Township over a stream on a heavily traveled 2-lane road, it is now part of the federal highway system. The west side of the bridge abutted a non-extant stone mill. A modern stringer bridge (1129154) over the flood plain is now contiguous to the west side.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. Princeton Battlefield / Stony Brook Village Historic District 10/15/1966, amended 11/21/1979 10/10/1989. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-proportioned 3-span rubble-coursed stone arch has ring stones and a low stone parapet. One of several ca. 1800 stone arch bridges, it is a large and impressive example of late-18th century engineering. The bridge is located in the Princeton Battlefield/Stony Brook Village District Extension (1989), but it is not rated. It was built within the period of significance of the district and should be considered a contributing resource based on its age, structural type, and history.

INFOR MATION

Bibliography:

"Princeton Battlefield/Stony Brook Village Historic District Extension" National Register Nomination. 1972, 1977. NJHPO.

Physical Description: The handsome rubble-coursed fieldstone arch bridge spans meandering Stony Brook on the western edge of Princeton. It carries heavily traveled two-lane US 206. The three-arch span has the largest opening in the middle with slightly smaller flanking arches. All have a ring stone band with no defined keystone. The bridge was built with a slight rise and has solid stone parapets. It has been widened, and the intrados have been covered with a shotcrete material. While the 82'-long bridge has no doubt been rebuilt over the years, the work has been in such a manner as to perpetuate the original scheme.

Historical and Technological Significance: The impressive 3-span barrel arch stone bridge was constructed in 1792, according to its plaque, on what was the main road (formerly known as the Kings Highway) from Philadelphia to New York. The bridge is one of three 1790-1810 multi-span stone arches in the vicinity, with the one across the Millstone River at Kingston being longer (four spans) and better preserved.

Stone arches represent a significant advancement in regional development for the bridge type reflects the progress and prosperity of the region. Due in large part to the quality of construction and the longevity of the technology (early bridges were frequently widened rather than replaced), a good number of late-18th and early-19th century stone arches survive in the state. The US 206 bridge is a representative example of that type, and as such is an important element in the historical development of the Princeton area. It is also a contributing resource in the Stony Brook Village Historic District.

Boundary Description and Justification: The bridge is located within a listed historic district, so the span and the surrounding acreage is evaluated as significant. Please refer to the map on file with the 1989 National Register nomination for the exact district boundary.

SETTING / CONTEXT In the middle of the John Fitch Redevelopment Project in downtown Trenton, the bridge is on the river side of the War Memorial Building. It links John Fitch Parkway (NJ 29) with Memorial Drive and Lafayette Boulevard. It is also adjacent to the park along the Delaware River. The area south of the bridge is dominated by undistinguished large modern office buildings.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Built in 1940 to ease traffic congestion in the center of Trenton, the well-detailed rigid frame bridge was designed by Harry Kersey to blend with the War Memorial building. Finished with glazed ceramic tile decorations and a geometric balustrade, the span is an example of the City Beautiful movement-inspired project. Rigid frame bridges are a common structural type in the 1920s and 1930s, and while not well represented in Mercer County, they are throughout the southern half of the state.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The inaccessible bridge carries two lanes and sidewalks over Amtrak's electrified line (Northeast Corridor) in a late-19th century residential area of the city. The area is dominated by 2- and 3-story row houses. The rail right-of-way is a brownstone retaining wall-lined undercut. A high concrete sidewalk protective barrier blocks any view of the railroad from the bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Although located over the historic right of way of the Camden & Amboy, the first line in the state to connect Philadelphia with New York City, the bridge is not significant. It is a rolled I beam stringer with a 7' high concrete parapet supported on ashlar abutments that continue as the retaining wall lining the roadway. The bridge is not historically or technologically distinguished, and it is of newer construction than the surrounding neighborhood.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge is located in the center of Trenton and carries a 4-lane plus sidewalks main street over 4 tracks of Amtrak's Northeast Corridor, electrified through the area in 1933. The street has been extensively redeveloped, so there is no NR district potential. The bridge is also of later construction than any historic buildings in the area. The undercut right-of-way is lined with a brownstone retaining wall. The bridge crosses the 1860s realignment of the Camden & Amboy RR.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span deck plate girder overpass is supported on ashlar seats and abutments that are part of the continuous brownstone retaining wall that lines the depressed road bed. A high plain concrete parapet encloses the sidewalks, and it has been reinforced (made deeper) on the inner face. The bridge is technologically undistinguished and the setting has lost its historic significance through redevelopment.

SETTING / CONTEXT The bridge is located in downtown Trenton and carries a 2-lane street over the main electrified line of Amtrak's Northeast Corridor. The depressed right-of-way has a brownstone ashlar retaining wall. The west end of the bridge rests on the 1869 stone arch across Assunpink Creek. The bridge is in full sight of the Pennsylvania Railroad's Trenton passenger terminal (now NJT). Surrounding area has been cleared and/or redeveloped.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The heavily skewed pin-connected double-intersection Pratt thru truss is a rare example of an unusual type. It stands in well preserved condition although a modern aluminum curb barrier covers the lower portion of the truss. The bridge was rehabilitated in 1981. In addition to its engineering significance, it is part of the historic transportation networks in Trenton, a town that grew because of and in response to transportation systems.

INFOR MATION

Bibliography:
Sanborn Insurance Maps, 1890-1923.
A. G. Lichtenstein Project File.

Physical Description: The 10 panel pin-connected double intersection Pratt skewed thru truss bridge is a half hip with the inclined end post and top chord composed of steel channels and plates. Deep trusses designed for heavy live loads, the bridge has upper and lower lattice sway bracing. Laced channels make up the verticals, and the diagonals are bar stock while the counters are rods. The bridge was strengthened in 1981 by post tensioning the trusses with cables. New stringers and wearing surface were also installed as was an aluminum safety shape barrier, attached to the flooring system, not the trusses. The remedial work is not intrusive. The bridge is supported on ashlar abutments that predate the present span. The northeast side bearings rest on the 1869 stone arch that crosses Assunpink Creek.

Historical and Technological Significance: The well-preserved skewed Pratt thru truss bridge was built in 1891 (fabricator unknown) after plans developed by the Pennsylvania Railroad's Office of the Chief Engineer (William H. Brown). It stands as a good example of late-19th century pin-connected metal truss technology and a truss type (double intersection Pratt or Whipple) that is not common. The truss type as well as its depth reflect the anticipated loading the bridge needed to support. Using the 1869 2-span stone arch at its northeast end as its seat, the truss bridge and the stone arch work in tandem to carry a local street over four tracks of the former Pennsylvania Railroad (Amtrak's main electrified line) and the channeled creek the tracks parallel. The pair represent the two dominant bridge technologies of the 19th century and as such are an important record of 19th-century technology.

The truss bridge was apparently installed when the Pennsylvania Railroad four-tracked its main line through Trenton. The right-of-way was established in 1862 when the Camden & Amboy Railroad (absorbed by the Pennsylvania system in 1871) realigned and thus straightened its route through the city. At that time the station was moved to S. Clinton Street. What type of structures serviced the crossing of the tracks and creek prior to 1869 are not known. Assunpink Creek originally crossed under the tracks between the vehicular bridge and the station. The creek was realigned in its present configuration prior to 1891.

A. G. Lichtenstein and Associates prepared bridge rehabilitation plans for NJDOT in 1979, and the work was done in 1981. The aluminum safety shape protects the lower portion of the trusses and the pin connections (not visible but still in place). Any replacement of original/early members was done in kind.

Boundary Description and Justification: The bridge is individually eligible, as is the contiguous stone arch bridge (1100052) that forms the north abutment of this bridge. The two bridges together form one resource that works in tandem to cross the creek and the railroad tracks that parallel the creek. The stone bridge was modified to accommodate the erection of the metal truss bridge. The metal truss bridge was built as part of the Pennsylvania Railroad's improvements of the station and right-of-way, but the setting has been changed greatly with the removal of the historic stations and surrounding buildings. thus, the historic boundary is limited to the substructure and superstructure of the metal truss and stone arch bridges.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The overpass is located in an architecturally significant late-19th century residential area in full view of the 1876 Hopewell railroad station that was listed in the National Register as part of the 6/22/84 thematic station nomination. The bridge, located to the north of the station, was not part of the nomination. Originally crossing at least two tracks, only one track remains. The overpass contributes to the historic character of the area.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Potential Historic District. May contribute.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The partially encased thru girder bridge with floor beams is supported on concrete abutments and is just north of the National Register-listed Hopewell Railroad station. In addition to the original lattice railing, the concrete jack arches between the floor beams and blocks for blast plates survive. The bridge is an integral part of the station development and its years of operation, and is individually eligible for listing in the National Register of Historic Places under Criteria A and C. Additionally, it is considered a contributing resource to a turn-of-the-century residential area with NR district potential.

INFOR MATION

Bibliography:
Lee, Warren. Down Along the Old Bel-Del. 1987.

Physical Description: The partially encased built up deck plate thru girder bridge on reinforced concrete abutments is well preserved and carries a 2-lane street over two tracks (only one remains). It is just north of the 1876 Hopewell station. The original lattice railing survives on the cantilevered sidewalks. No modern pedestrian protection barrier has been installed. The underside of the bridge is encased, and concrete jack arches are used between some floor beams while others have the concrete panels to which the blast plates were attached. The tie rods running between the stringers are also encased in concrete. The encasing is deteriorating. The girder is constructed of Pencoyd steel.

Historical and Technological Significance: The well-preserved deck plate thru girder overpass is located in a architecturally distinguished late-19th century residential area that appears to have National Register district potential. It is also located just north of the well-preserved 1876 Hopewell station that was listed in the 1984 thematic Operating Passenger Railroad Stations National Register nomination. Although the 1918 bridge was erected by the American Bridge Company after the station and most of the homes were constructed, the span does fall within the period of significance of the station (operating in 1984) and perhaps the neighborhood itself. The bridge is thus an eligible resource because of its historic association with the 1876 station, its location in a well-preserved, architecturally significant residential district, and its contribution to the historical development of that neighborhood. It is also a good representative example of a structural type that was commonly used for railroad overpasses in the early to middle 20th century. The jack arch strengthening and encasing was used by the Reading Railroad, builder of the bridge, on their 1918 Bridge Street Warren thru truss span in Manville (Somerset County, 1850167).

The overpass is one of the few in the county to survive with its original railings intact. Their Eastlake style contributes to the historic character of the streetscape.

SETTING / CONTEXT The bridge is located over an abandoned railroad right-of-way near in an urban area near the capitol complex. Some of the original brick pavers survive.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 11/29/90

SUMMARY The encased stringer bridge with a plain concrete balustrade is not historically or technologically significant. The ashlar abutments are earlier than the span. The bridge was determined by the SHPO to be neither historically or technologically significant. It crosses the Belvidere Delaware RR, a subsidiary of the Camden & Amboy built parallel to the canal in the 1850s. The line became part of Conrail in 1977 and was abandoned in 1979.

SETTING / CONTEXT The bridge carries a 2-lane local street over the abandoned right-of-way of the former Belvidere-Delaware Railroad, a line built as a subsidiary of Camden & Amboy in the 1850s. It is located in a once-distinguished late-19th century residential area, but there are alterations to most of the structures. The undercut right-of-way is poorly maintained.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The short encased single-span thru girder with floor beams is supported on scored concrete abutments with wing walls. The cantilevered sidewalks have paneled concrete parapets. The bridge is technologically and historically undistinguished and is a representative example of a common structural type. The rail line, which ran through Lambertville to Phillipsburg and beyond, crossed at grade until after 1890.

SETTING / CONTEXT Located immediately south of the 1930s realignment of US 206 on a section of the former Lincoln Highway, the bridge is now separated from the newer span, which carries US 206, by a wooded island. The surrounding area is dominated by scattered period homes. The span is located in a high traffic area on the old Lincoln Highway also known historically as the Lawrenceville-Princeton Road.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel pin connected Pratt pony truss is one of several that survive in Mercer County. It is a representative example of a once-common type that has increased in value since many have been lost. No plans survive to document the fabricator or designer. The bridge appears to have no distinctive details, but the 26" deep floor beams are unusual and may be that size because of the width of the bridge. The ashlar abutments are original. It is significant for its historical associations and type.

INFORMATION

Bibliography:
Mercer County Engineers Office. Transfer File # 543.19.
Hokanson, Drake. The Lincoln Highway: Main Street to America. University of Iowa Press, 1988.

Physical Description: The 4-panel pin-connected Pratt pony truss appears to survive in reasonably complete condition despite its location at a heavily traveled intersection adjacent to US 206 and the number of times it has been damaged from impact. The approaches are sharp curves in both directions. The top chord and inclined end posts, severely buckled in places, are built-up box members with battens on the underside while the verticals are back to back angles joined by lacing. Double eyebars form the diagonals, and rods with forged loops are used for the counters. U-hangers carry the built-up 26'-deep floor beams, which appear to be original, but the stringers that carry the plank deck are post-1954. Lateral bracing is connected to a pinnel on the floor beam. The original pipe railing survives on the south side only. A modern beam guide rail has been added to the upstream side. The bridge does not appear to possess any noteworthy components. Outrigger braces have been added. The bridge rests on ashlar abutments.

Historical and Technological Significance: The light pin-connected Pratt pony truss was built in 1896, and it is significant as the sole survivor in the county of a full hip pin-connected pony truss bridge and for its historical association with the Lincoln Highway (Criterion A, C). It is located on the Old Princeton-Lawrenceville Road, now known as Fackler Road, that was part of the Lincoln Highway, an early attempt to establish a national coast-to-coast route. Although the bridge was not built as part of the development of the Lincoln Highway, it is evocative of the bridge types in use when the highway was its heyday. The fabricator of the bridge is not recorded in the Mercer County Engineer's records, and a plaque shown on the top cord in a 1953 photograph is gone. The only surviving plan of the structure is for the ashlar abutments, and it was prepared in 1896 by R.B. Budd, Engineer. The bridge, however, appears to survive in fairly original albeit battered condition. It is the only example of a pin-connected full hip Pratt pony truss in the county. The two other pin-connected Pratt pony trusses in Mercer County are the half-hip form. The full hip is less common configuration.

A coast-to-coast rock highway was the dream of Carl G. Fisher, president of the Prest-O-Lite Company, manufacturer of carbide headlights and founder of the Indianapolis Motor Speedway. In 1912, he promoted the idea of a privately financed cross-country improved road with car manufacturers. It was Henry R. Joy, president of the Packard Motor Car Company who came up with the suggestion to name the route in honor of Abraham Lincoln. In an era when there were few improved roads outside of congested areas, the concept of a paved interstate road caught on quickly, and contributions from companies and private individuals poured into the Lincoln Highway Association's office in Detroit. One prominent non-supporter was Henry Ford, who believed that good roads were a public responsibility. His lack of support was critical, and by 1914, it was apparent to the leadership that the goal of 10 million dollars to build the Lincoln Highway would never be realized.

The association's efforts were thus directed to marking the route, which was composed of existing roads like the section of the Old Princeton-Lawrenceville Road. The Lincoln Highway, one of several memorial highways of its day, was to link New York with San Francisco, and the selected route passed through twelve states. Most of the highway in New Jersey was along the old Kings Highway, coming across from Elizabeth to Princeton, and then down to Trenton, cross the Calhoun Street Bridge, and then on to Oxford Valley and Langhorne. To encourage locally funded improvements of the route, the association, like the federal Bureau of Public Roads and some state highway departments, built short sections of concrete roadway to serve as object lessons on the benefit and construction technique of a permanent roadway.

With the passage of the 1921 Federal highway Act and its funding of a "connected system of highways, interstate in character," the need for privately promoted coast-to-coast route was no longer as urgent. The association knew that its days were numbered, and in 1926, when the federal numbering system was put into operation, the Lincoln Highway ceased to be a designated route. Most of its length in New Jersey became US 1. When that right-of-way was itself bypassed, the old Lincoln Highway became parts of US 206 and NJ 27. The Fackler Road bridge was bypassed by an improved alignment and a new bridge (1129153) in 1923. The Lincoln Highway Association ceased "active and aggressive operations" December 31, 1927.

Boundary Description and Justification: The significance of the bridge is based, in part, on its location on the historic right-of-way of the

Lincoln Highway, an early attempt to create a transcontinental route. In New Jersey the highway was comprised of sections of old, and often historic, roads. The bridge and the roadway right-of-way of the old Lincoln Highway are both evaluated as significant. The bridge is also significant in its own right.

SETTING / CONTEXT The bridge carries 3 lanes of US 1, a wide shoulder and 2 sidewalks from an undistinguished residential area of New Brunswick to a late-20th century residential area in Edison Township. It crosses an undeveloped strip along the Raritan River and a 2-lane service road. The bridge originally carried two directions of traffic, but a new parallel span carries southbound traffic. Morris Goodkind won an architectural award presented by the ASCE in 1930 for this bridge design.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-preserved 15-span ribbed arch bridge is composed of 6 open spandrel arches and 9 closed spandrel arch approach spans. Among the earliest of the large state-designed spans to emphasize the moldable properties of concrete in its handsome detailing, the bridge reflects the New Jersey State Highway Department Bridge Division's emphasis on sound bridge engineering coupled with aesthetics. In 1969, the bridge was posthumously named for its designer, Morris Goodkind, Chief Bridge Engineer.

INFOR MATION

Bibliography:

Condit, Carl W. American Building Art. 1961.
Proceedings of the American Society of Civil Engineers. August 1930.
Hess, Jeffrey A. and Frame, Robert M. Wisconsin Stone arch and Concrete Arch Bridges. 1986.
Plowden, David Bridges: The Spans of North America. 1974.

Physical Description: The well-proportioned open-spandrel reinforced concrete ribbed arch bridge is 1902' long. The 15-span structure is composed of 6 open spandrel arch main spans and 9 closed spandrel arch approach spans. The reinforced concrete structure has 3 ribs in each span. The spandrel arches over the elliptical main span arches are semi-circular, as are the approach arches. The handsome structure is marked by four classically styled towers at the corners, each with an inset commemorative plaque from 1929. The sidewalks are enhanced by the inclusion of exedras at the main span piers, with benches cast into the concrete balustrade. Original luminaries over these bays were replaced in 1971 with modern standards. The concrete deck was replaced in-kind that same year, and guiderails were added at the curblines. With the exception of the 1971 rehabilitation, the bridge remains as it was originally designed.

Historical and Technological Significance: The US 1 open-spandrel ribbed arch bridge is significant because it represents the quality designs that Morris Goodkind(1869-1968) produced throughout his career as the State Bridge Engineer. It is one of approximately 10 open-spandrel arch bridges in New Jersey, a bridge type that defines the highest level of refinement in reinforced concrete arch technology. The well-preserved bridge represents Goodkind's emphasis in the New Jersey State Highway Department Bridge Division to create aesthetically pleasing concrete structures prior to World War II. The moldable qualities of the material were used to create an architectural masterpiece at the same time that its structural qualities were used to efficiently carry a major highway across a wide river. The reinforced concrete arch was capable of relatively long spans while providing graceful and dynamic forms.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type. A massive structure, the open spandrel arches span 233 feet with virtually no steel reinforcement in the two ribs. In the first two decades of the 20th century, railroads began using reinforced concrete to construct large viaducts across rivers and valleys to eliminate steep grade changes. The length and number of spans increased to create massive structures that dominated the landscape. The Tunkhannock Viaduct (completed 1915) of the Delaware Lackawanna & Western RR in Nicholson, Pennsylvania remains one of the greatest bridges in America. It is a ten-span open spandrel reinforced concrete arch, 2375 feet in total length, each span 180 feet in clear span, and rising 240 feet above the creek bed in the valley floor.

The US 1 Bridge was completed 14 years later in 1929, but is comparable in size and beauty. The main arch spans are 202 feet clear span, though they rise only about 100 feet above the water level of the Raritan River. The bridge is 1902 feet in total length.

Morris Goodkind, designer of the bridge, was a graduate of Columbia University. He worked for the New York City Public Service Commission in the development of the subway system before working on bridge designs for engineering firms and Mercer County, NJ. In 1922 he joined the New Jersey Highway Department, and became the Chief Bridge Engineer in 1925, a post he held through 1955 when he retired to private practice.

The 1920s and 1930s were a time of great expansion of the state's highway system required many bridges to be built. Goodkind emphasized the need for aesthetically pleasing as well as structurally sound bridges. He brought in Arthur Lichtenburg to develop an architectural section in the Bridge Department. Many of the grade elimination bridges of the 1930s and 1940s in congested areas were detailed with Moderne and Deco pilasters and entablature due to the influence of Goodkind and Lichtenburg. The same structures had encased stringers, the most common type built during Goodkind's term. He emphasized the encasement for protection of the steel from the elements, a valid assertion considering the number and condition of such structures remaining in New Jersey.

A. G. Lichtenstein & Associates, Inc. performed initial survery.
NJDOT updated data 03-01-2001.

Correction Updates Etc should be sent to
Correspondence.Unit@DOT.State.NJ.US

November 12, 2002

While working for the state, he served as a consultant on bridge construction for the War Department. Upon his retirement as Chief Bridge Engineer, Goodkind became a consultant with the firm of Goodkind and O'Dea in Manhattan. He was internationally known and respected for his bridge engineering. He had been active in local and national engineering societies, and won several awards for the designs of bridges.

Goodkind was awarded the Phoebe Hobson Fowler Architectural Award by the American Society of Civil Engineers for the design of the US 1 bridge. To recognize the contribution which Goodkind made to the State of New Jersey, the name of the bridge was officially changed from the College Bridge to The Morris Goodkind Bridge on April 25, 1969, following his death the previous September.

SETTING / CONTEXT The bridge is located in the earliest documented cloverleaf interchange in New Jersey. It carries US 1 and US 9 (4 lanes of divided highway) over NJ 35 (4 lanes divided by raised grassy median strip) in a 20th century commercial area. The bridge is the center point of the interchange, with the four loops and four ramps surrounding it.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 6/6/91

SUMMARY The well-detailed 2-span stringer bridge on a concrete substructure is an integral part of the earliest documented cloverleaf interchange in the state. It is technologically significant as the prototype of a well-established solution to traffic engineering. New Jersey was a national leader in the development of grade crossing elimination's, and the Woodbridge cloverleaf survives as a well-preserved example of the innovative solutions the State Highway Department developed in the 1920s.

INFOR MATION

Bibliography:

Hill, C.S. "Intersection Design a Primary Highway Problem in New Jersey", Engineering News-Record, November 26, 1931.
NJDOT, Memorandum, To: Record, From: Suzanne Sczepkowski, May 8, 1991.

Physical Description: The two-span encased stringer bridge is supported on concrete abutments and a pier. The fascia of the bridge is adorned with moderne pilasters at the abutments and at the pier. The pilasters rise to meet the posts of the concrete balustrades at both sides of the structure. Modern light posts have replaced the original fixtures at the four corners of the bridge, and a jersey-type concrete barrier has been added at the centerline of the roadway.

Historical and Technological Significance: The bridge was determined eligible under Criteria A and C "as part of the cloverleaf and noted that individually it is undistinguished." The bridge is located in the Woodbridge Township intersection of US 1 & 9 and NJ 35. This intersection is the first cloverleaf interchange constructed in New Jersey. The cloverleaf design was one answer to the problem of grade intersections which created traffic problems as the automobile came into high usage. Engineering News Record reported that the "four-leaf-clover permits each main roadway to carry 100 per cent of its capacity through the intersection." This interchange was a pioneering engineering effort that is used as a model today, over 60 years after the original.

Boundary Description and Justification: Because the bridge is eligible only as part of the interchange, the intersection of the right-of-ways of the highways included in the cloverleaf should be the boundary of eligibility.

CONSTRUCTION DT 1942 **ALTERATION DT** 1982 **SOURCE** INSCRIPTION

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge is located in a mid to late-20th century commercial area. It carries a heavily travelled 6-lane divided highway with sidewalks over a 4-lane county route. US 9 was widened in this area in 1982.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span stringer bridge has Moderne detailing on the concrete substructure that is more stylized than on other abutments ca. 1940. The detailing was not repeated when the structure was widened in 1982. The original railing has been replaced by a new concrete parapet and fencing. A Jersey-type concrete barrier divides the two-directional traffic. The bridge is not technologically or historically distinguished. It is a common bridge type and the original design integrity has been lost.

SETTING / CONTEXT The bridge is located in a wooded and late-20th century industrial setting. It carries US 9 and NJ 35 (4-lane divided highway) over active Conrail tracks. The line was opened in 1832 by the Camden and Amboy RR for freight and passenger business. Passenger service was soon rerouted to what is now known as the Northeast Corridor, but these tracks carried freight through 1965. The tracks were electrified in 1937, and the overhead lines remain.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Camden & Amboy Railroad Main Line Historic District. Contributing.

CONSULT DOCUMENTS SHPO Opinion 1998, Letter 03/12/01.

SUMMARY The 1937 3-span stringer bridge bears on an unadorned concrete substructure. The bridge has a typical balustrade over the end spans and a high paneled parapet (catinary barrier) over the main span, crossing the electrified tracks. The paneled parapet posts have decorative faience tiles, not an uncommon detail on 1930s State-designed bridges. The bridge, nearly identical to a 1934 example (1119150), is not technologically or historically distinguished, being one of over 40 pre-WW II stringer bridges remaining in the county. Rail lines in New Jersey were electrified starting in the early 1910s. The bridge is within the boundaries of the National Register eligible Camden & Amboy Railroad Historic District, but it has not yet been determined to be a contributing element.

SETTING / CONTEXT The bridge carries four lanes of divided highway (US 9) and one sidewalk across two wide lanes at the south side of Victory Circle. NJ 35 separates from US 9 at the circle to cross the Raritan River. The bridge has been determined eligible for listing in the National Register because it is considered a contributing element to the Edison Bridge (US 9) over the Raritan River. The structure number posted on the bridge is 1208158.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Agreed Edison Bridge. Contributing.

CONSULT DOCUMENTS SHPO Finding 11/22/91, Letter 6/30/95.

SUMMARY The one span stringer bridge sits on concrete abutments with banded detailing. The posts at the corners of the abutments are scored vertically and stepped at the top, flanking the typical concrete balustrade. The well-detailed bridge is a representative example of a common bridge type in the county, as it is one of over 40 extant pre-World War II stringer bridges in Middlesex County. It is not technologically or historically distinguished.

INFOR MATION

Bibliography:
New Jersey State Highway Department Annual Bridge Reports, 1939, 1940.
Letter from Andras Fekete, NJ DOT BEA, to Ms. Nancy L. Zerbe, Deputy SHPO, ONJH, Dated November 22, 1991.

Physical Description: The one span encased stringer bridge is supported by concrete abutments. The substructure is banded, with vertically scored posts at the corners of the abutments rising into stepped posts of the standard design concrete balustrade.

Historical and Technological Significance: The bridge is not a significant structure as it is only a representative example of a very common bridge type. The detailing of the structure is similar to other 1920s and 1930s grade elimination bridges in Middlesex County. The bridge designers used a typical solution to a common problem for this structure.

The bridge was determined eligible by the SHPO because it was "an approach integral and not separate to the main bridge (Rt. 9 over the Raritan River - Str. No. 1209-155) which is eligible. Therefore, this structure would be a contributing element to the bridge." The two bridges at Victory Circle are approximately half a mile from the main bridge, and no more tied to the structure than any other grade elimination bridge on NJ 9 or NJ 35 which are several miles from the Edison Bridge. The contract for the construction of the Victory Circle bridges was separate from the contracts for the Edison Bridge, although all were completed in 1940.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER** ENGLISH & NESTO COMPANY

SETTING / CONTEXT The bridge carries 4 lanes of heavily travelled roadway across the Raritan River, a marshy area, and an industrial area on the north bank of the river. Victory Circle is just to the south of the bridge, at the intersection of US 9 and NJ 35. The Edison Bridge was determined eligible because the main spans are continuous over 3 spans, a feature which is unusual for bridges of this proportion. 2 bridges in Victory Circle were determined eligible as approaches to this structure.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 11/22/91

SUMMARY The deck girder bridge is well-preserved, well-detailed, and is an early example of a long-span continuous girder bridge. The approach spans are simply supported 7' deep girders, while the 9 main spans are 3-span continuous, with girders as deep as 21'. The concrete pier columns and struts are nicely detailed from top to bottom. The posts at the abutment display a large tile of the state seal, with more tile on the approach railing. Similar tile work was seen on only one other span (1210155).

INFOR MATION

Bibliography:
Condit, Carl W. American Building Art: The Twentieth Century. 1961.
Fox, Robert. Interview with Mary McCahon, 4/7/92.
"Morris Goodkind, Bridge Builder, Dies", The Daily Home News, New Brunswick, N.J., Saturday, September 7, 1968.

Physical Description: The 29-span steel deck girder bridge is supported on reinforced concrete piers and abutments. The nine longest spans are over the river, and are composed of three pairs of three-span continuous girders. The massive girders are as deep as 21 feet at the mid-river piers. The approach spans are simply supported girders that are typically about 7 feet deep. All of the spans have floor beams and stringers below the concrete deck.

The pier columns and the struts are nicely detailed with scored bands and stylized paneling just below the bearings. The approach balustrades are elaborately detailed with decorative tiles. The posts at the abutments bear a circular tile at the seal of the State of New Jersey. A similar tile was seen on a few other bridges in the state (1210155, 1606158, 1607163). Metal railings line the roadway across the bridge. A concrete jersey-type barrier has been added along the centerline of the road.

Historical and Technological Significance: The bridge was determined eligible by the SHPO on 11/22/91 because of its size, its type, its age, and its association with Morris Goodkind. It was found eligible under Criteria C and B. It is well-preserved and well-detailed, and is an early example of a large-scale continuous deck-girder bridge.

The 29-span bridge is a significant and early example of its type. Although deck girder bridges were common in the early 20th century, the design of a three-span continuous system of this magnitude was not common. This 1939 structure took a small-scale bridge type to a large-scale proportion. The well-preserved structural components of the bridge function today as they did when it was designed.

Morris Goodkind (1888-1968), responsible for the design of this bridge, was a graduate of Columbia University. He joined the New Jersey Highway Department in 1922 and became the Chief Bridge Engineer in 1925, a post he held through 1955. His tenure with the State Highway Department coincided with the state's dramatic expansion of the state highway system that required many new bridges.

Goodkind emphasized the need for aesthetically pleasing as well as structurally sound structures. He brought in architect Arthur Lichtenburg to develop an architectural section in the bridge department. Lichtenburg was with the department until the late 1960s. The two men were responsible for the fine detailing that characterizes New Jersey's concrete spans. Many of the grade elimination bridges of the 1930s and 1940s were detailed with Moderne and Deco pilasters and entablature as well as faience tile decoration.

The Edison bridge is a fine example of the attention to aesthetic detail that these men stressed in bridge construction. The elaborate tile work as well as the detailed concrete of the substructure attest to the emphasis on aesthetics on State Highway Department-designed bridges.

Boundary Description and Justification: Because it is the bridge itself that is eligible, the boundary is limited to the superstructure and the substructure of the bridge itself. The existence of 2 single-span stringer bridges in Victory Circle at the south approach to the bridge is not relevant to the eligibility of the Edison Bridge.

SETTING / CONTEXT The bridge is located in a residential area which has been converted to commercial use. It carries a 4-lane divided highway with no shoulders or sidewalks across a 3-lane city street. The bridge was built as part of a grade separation project of the mid-1930's that resulted in bridges carrying US 9 over local streets and railroads.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The stringer main span and slab approach spans bridge sit on a concrete substructure. It is a representative example of the well-detailed overpasses produced by the State Highway Department in the pre-WW II era. The abutments are detailed with fluted pilasters at the corners, and the back walls have decorative panels. The balustrade is a standard design. The well-proportioned bridge is well preserved, but it is not technologically or historically distinguished.

SETTING / CONTEXT The bridge is located in a wooded area with late-20th century office buildings nearby. The brook is dammed on both sides of the bridge to create a pond. It carries northbound traffic across the pond. The bridge was being redecked in 1992.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 11/22/95

SUMMARY The well-proportioned 3-span open spandrel ribbed arch bridge with spandrel columns was altered in 1992 when the original balustrades were replaced with parapets, but it remains a significant example of an uncommon type. It is one of approximately 8such bridges designed and built by the state between 1929 and 1939. The bridge is technologically and historically significant.

INFOR MATION

Bibliography:
Condit, Carl W. American Building Art. 1961.
Hess, Jeffrey A. and Frame, Robert M. Wisconsin Stone Arch and Concrete Arch Bridges. 1986.
Fox, Robert. Personal Interview with Mary McCahon.

Physical Description: The 3-span open spandrel arch bridge has a total length of 228 feet between abutment faces. The center arch has a clear span of 76'-6". The 5-ribbed arches are parabolic, with slender spandrel columns supporting the floor beams and deck. In 1992 the reinforced concrete deck was replaced in-kind. It is directly tied to the floor beams by steel reinforcing. The original balustrade design is echoed on the fascia of the new concrete Jersey-type barriers. Large concrete pylons remain at the four corners of the bridge, along with the original approach balustrades.

Historical and Technological Significance: The three-span open spandrel reinforced concrete arch bridge over Weston's Mill Pond is a representative example of the past and present emphasis on sound bridge engineering coupled with aesthetics by the New Jersey State Highway Department Bridge Division. It was designed in 1931 using state-of-the-art bridge technology to create a structure that enhanced the beauty of the area. In 1991, the deck and original parapet were replaced with a similar deck and a Jersey-type barrier.

Morris Goodkind oversaw the design of this bridge as Chief Bridge Engineer of the New Jersey State Highway Department. Several bridges of this type were constructed in New Jersey between 1929 and World War II, and some of them are more complete examples of the important bridge type (1203150, 1606158, 1607168, 1810170). The designs were greatly influenced by the design of the College Bridge (1203150), the most important State Highway Department-designed open spandrel arch bridge, carrying US 1 over the Raritan River.

The first reinforced concrete bridges were designed and patented around the turn of the century. Concrete arch bridges were reinforced with steel to reduce cracking in the concrete and to eliminate the massiveness of the structures. One technique of material reduction was opening the spandrel vaults in lieu of filling them with earth or concrete. Since the vaults could be empty, spandrel walls did not need to be solid, but could be opened as long as the load of the deck was brought down to the arch with spandrel piers. As the technology progressed, solid barrel arch design was often replaced with ribbed arches, further reducing the volume of material. Open spandrel arch bridges were built as early as the first decade of the 20th century. They are representative of the highest level of refinement in the design of reinforced concrete arch bridges.

SETTING / CONTEXT The bridge carries 4 lanes of traffic and 2 sidewalks over the Raritan river in downtown New Brunswick. The former Delaware 7 Raritan Canal flows under the west approach. The setting is not distinguished. Apartments are located on the east side of the river, and urban-renewal areas and access roads to highways characterize the west or New Brunswick side.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. D&R Canal. 05/11/1973. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY Built ca. 1890 as a 32'-wide, 7-span brick arch with well detailed coursed ashlar spandrel walls and gauged ring stones, the bridge has been altered several times. In 1924, to alleviate vehicular congestion at the crossing, the State widened the bridge with an arched concrete addition to the upstream side. The deck girder approach spans were also widened in kind. The need for widening demonstrates the structure's historical associations with the economic vibrancy of New Brunswick that was, and is, an important regional commercial center. The 1929 widening, despite its use of a different masonry material, is compatible with the arch design and construction of the original structure. This arched concrete addition has gained significance over time and does not diminish the integrity of the structure. The bridge was widened again in 1954, and in 1985 the deck and railings were replaced. The brick arches have been gunited. Despite these changes, the bridge retains its original appearance on the upstream elevation below the bridge deck. This structure is individually eligible for listing in the National Register of Historic Places under Criterion C, as an example of a large multi-span arched viaduct, and under Criterion A, as a contributing element of the Delaware and Raritan Canal Historic District.

CONSTRUCTION DT 1909 **ALTERATION DT** 1922 **SOURCE** PLANS

DESIGNER/PATENT AMERICAN BRIDGE CO. **BUILDER** AMERICAN BRIDGE COMPANY

SETTING / CONTEXT The bridge is located in a late-20th century residential and small commercial area. It carries a 2-lane state route and two sidewalks over one track of depressed, inactive rail line, ConRail's Port Reading Branch. The line was in service primarily as a coal hauler for the Reading RR from 1892 until 1983, when the coal operation was discontinued. Conrail obtained the Reading RR in 1976. The main line is still in use, but this branch probably went out of service in 1983.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span lattice web deck girder bridge rests on steel bents and concrete abutments. The uncommon superstructure was built in 1909, using only the fascia girders and bents. The center lattice web girder and its supporting columns were added in 1922 to increase the live load capacity as automobiles came into prominence. The 1909 railing has cast iron posts and latticed panels topped with filagree bands. The bridge is technologically important as one of the few examples of the type in the state.

INFOR MATION

Bibliography:
Waddell, J.A.L. Bridge Engineering. 1925.
NJDOT Plan File.

Physical Description: The skewed lattice-web deck girder bridge was built in 1909, using two girders on riveted steel bents. In 1922 a third girder was added at the centerline of the bridge. New steel columns were erected off-line from the bents, and braced into them. The girder webs are composed of diagonally riveted angle sections slanted in opposite directions on opposite faces of the girder. Rolled floor beams and encased steel stringers support the concrete deck. Timber plank sidewalks are cantilevered from the fascia girders. The 1909 railing has cast iron posts, and lattice panels with filagree top sections under the round tub top rail. Some sections of the railing are misaligned or missing.

Historical and Technological Significance: The Middlesex Avenue lattice-web deck girder bridge is technologically significant as a good example of an early bridge type that has become rare in New Jersey (Criterion C). It is the only documented lattice- or open-web girder in Middlesex County, and one of less than a half dozen highway examples known in the entire state. Two others exist in Hudson County (0900011 & 0950163), but each of them has a different style of web lattice. By the 1910s, plate girders were becoming more widely used than open-webbed girders. The plate girder was stronger, easier to fabricate, and more readily available. The lattice-webbed girder is an example of "first-generation" technology used around the turn of the 20th century.

The American Bridge Company, builder of many bridges throughout the state, is the fabricator of this structure. It was built for the Port Reading Railroad. Their plans from 1909 show the span with only two girders, and only two columns per bent. A plan sheet from the Port Reading RR's office dated 1922 details a bridge strengthening and deck replacing scheme. The work to be done included an additional girder at the centerline of the bridge, with new columns connected to the bent supporting the girder.

The addition in 1922 of the center girder strengthened the bridge, allowing for an increased load capacity. The timber deck that was placed in 1922 was crowned for drainage, as the original deck had not been. The placement of the current deck is not documented. The bridge has retained the integrity of its original design, including the major bridge strengthening that occurred in 1922.

Boundary Description and Justification: The significance of the bridge is limited to the structure itself and not to the surroundings. The boundary of eligibility is the substructure and superstructure of the bridge, including the portions of the railing built during the original construction.

SETTING / CONTEXT The bridge carries a 3-lane state highway over a small stream through a mid- to late-20th century residential area. The highway parallels Amtrak's Northeast Corridor tracks, which are carried over the same stream by a stone-faced arch 20' to the east.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The original structure is a reinforced concrete deck arch that was built in 1919. In 1926, it was widened by adding stringers on the upstream side of the arch. Both sides of the bridge have a concrete balustrade, but with different construction date inscriptions. The ashlar abutment that supports the stringer addition is shared with the railroad bridge 20' upstream. The bridge is a representative example of common pre-World War II bridge types and is not technologically or historically notable.

SETTING / CONTEXT The bridge is located in a mid- to late-20th century industrial area along the Raritan River. An extensive dedication ceremony was held for the opening of the Victory Memorial Bridge. It was dedicated to the veterans of war from the State of New Jersey.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 12/19/94

SUMMARY The subdivided Warren thru-truss swing-span bridge still functions as it was originally intended. The original (or in-kind) gears and electric motors rotate the center-bearing structure. The approach spans are deck girders (9 spans) and stringers (44 spans). Concrete balustrades enclose the stringer spans, while the steel deck-girder and truss spans have a metal railing. The tender's house sits above the roadway at the center pier. The bridge is a large, well-preserved example of its type.

INFORMATION

Bibliography:
NJ DOT Bridge File: 1223150.
"Veterans Souvenir Program of the Dedication of The Victory Bridge as a State Memorial", Victory Memorial Bridge Celebration Committee, June 24, 1926.

Physical Description: The 53-span bridge is composed of a thru truss center-bearing swing span main span, 16 steel deck girder spans and 36 concrete stringer spans. The main span is a cantilevered subdivided Warren thru truss that is 360' from end to end. The riveted truss members are built-up of plates, angles, and channels joined by lattice bars. The center-bearing span pivots on an ashlar pier that has a concrete cap. The operator's house is located directly above the pier, over the roadway, in the truss bracing. The original crash gates are still operated manually when the bridge is opened.

The deck girder approach spans have floor beams and stringers supporting the deck. These 16 spans complete the river crossing on ashlar and concrete piers. The remaining 36 spans are stringers that are continuous over three spans. These spans form the approaches over land on concrete column bents. At the ends of the bridge are classically styled towers with luminaries. The lighting fixtures were replaced across the bridge in 1972, but the original brackets remain at these towers. New guiderails were placed along the curblines the same year. The sidewalks are enclosed by concrete balustrades on the stringer approach spans and by metal railings on the deck girder and truss spans.

The swing span operating mechanism survives in a complete state of preservation. The rack and pinion drive is activated by a series of reduction gears located below the span that are powered by the original direct-current electric motors housed in the operator's house. The power is transmitted vertically by a long line shaft from the elevated operator's house to the gear sets under the bridge. The control panels are original, but hydraulic wedges are now used in place of mechanical ones, and the brakes have also been replaced.

Historical and Technological Significance: The 360' center-bearing swing span bridge is significant as the largest and latest example of a highway bridge of its type in the State of New Jersey (Criterion C). The bridge is in a nearly complete state of preservation, with much of the original equipment still functional. The Victory Memorial Bridge, named to honor those who served in World War I, is a late example of the swing span type. The use of the Raritan River as a shipping lane necessitated either a moveable bridge or a high one. Documentation detailing the decision to use a time-tested technology like a swing span rather than a bascule or vertical lift span at the crossing has not been preserved. The width of the river at the point of the bridge allowed a swing span to be used without disturbing dock areas at the banks of the river. The channel width also allowed room for the large pivot pier needed at the center of a swing span. The swinging truss is a very powerful image for traffic both on the river and the highway. The bridge was designed by Clarence W. Hudson, a consulting engineer. The state of preservation of the bridge also makes it significant. The original operator's house remains in use over the roadway. In it are the electric motors which drove the bridge when it was first built, and from them come the gearing, which is arranged as it was originally. The structural components of the bridge are also well-preserved, with little evidence of rehabilitation. The truss has been well-maintained, as has been the superstructure of the approach spans. The most notable rehabilitation changes are those made for safety reasons, the new lighting and guiderails which were installed in 1972. The timber fenders require a consistent maintenance schedule that has resulted in in-kind replacement of deteriorated members. The overall condition of the structure has been very well preserved.

Boundary Description and Justification: The bridge is evaluated as distinguished individually, so the structure itself is the boundary of significance.

 # SPANS 3 **LENGTH** 165 ft **WIDTH** 66 ft

CONSTRUCTION DT 1941 **ALTERATION DT** **SOURCE** INSCRIPTION

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge is located in a mid- to late-20th century industrial area, and carries a 4-lane divided highway and 2 shoulders with narrow sidewalks over a single electrified track. The rail line is the ConRail's Jamesburg Branch. The line was built in 1864 from Monmouth Junction to Jamesburg by the Pennsylvania RR. It connected the NE Corridor to the United Companies (ex-Camden & Amboy) line, and was electrified around 1937 to allow electric coal trains to reach South Amboy.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span stringer bridge sits on concrete piers and abutments. The column bents are set on crash walls. The two end spans have common State-designed balustrades flanking a high concrete parapet on the middle span. The parapet has panels with filled corners between stepped posts. The bridge is not technologically or historically distinguished.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge is located in a mixed commercial and industrial mid to late 20th century area. It carries 4 lanes of a divided highway with mountable median, shoulders and narrow sidewalks over a 2-lane county route.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single span stringer bridge is set on vertically scored concrete abutments. The abutments have Moderne shallow pilasters on their faces, but not at the fascia corners. The concrete balustrade is of common design, with beam guiderails attached at the approaches. The bridge is not distinguished historically or technologically, being one of over 40 extant stringer bridges in Middlesex County built prior to World War II.

SETTING / CONTEXT The bridge is located in a single-family detached residential area of mixed-20th century construction but predominately modern construction. Two lanes of traffic cross the bridge over a small stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Listed. Listed. South Randolphville Road Bridge. 09/17/1999.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The two-span earth-filled arch bridge has a corrugated steel liner and stone spandrel walls. The balustrades are masonry, matching the spandrels, and topped by a clay-colored concrete cap across the balusters and on the posts. The bridge is more elaborately detailed than most other county bridges of the era. This structure is individually eligible for listing in the National Register of Historic Places under Criterion C. The anachronistic appearance of this steel arch bridge is achieved by the use of several design features which are totally unrelated to its structural functioning: stone veneers with an exaggerated keystone, projecting pilasters, a projecting belt course, and ornamental stone parapet walls with a decorative clay colored concrete cap. The variety of finishes which could be applied to this construction type, paired with its inherent affordability, were hallmarks of the strategies used to market this type, as borne out by literature of the period.

DESIGNER/PATENT ALVIN B. FOX **BUILDER** FERRO CONCRETE CO.

SETTING / CONTEXT The bridge is set in a residential area of early-20th century homes with late-20th century homes mixed in. The residential area surrounds a park which follows Ambrose Brook. The bridge carries three lanes of traffic and two sidewalks across the stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete deck arch bridge was built by the Ferro-Concrete Company, who built many arch bridges using patented Luten reinforcement systems. This bridge was designed by the county engineer using a simple reinforcement pattern, not a Luten patented system. The bridge was widened in 1960, though it is not obvious due to duplication of the original parapet. The bridge is the oldest reinforced concrete arch in the county, but is otherwise undistinguished.

INFORMATION

Bibliography:
Condit, Carl W. American Building Art. 1961.
Hess, Jeffrey A. and Frame, Robert M. Wisconsin Stone Arch and Concrete Arch Bridges. 1986.
United States Patent Office, Several patents granted to Daniel B. Luten, Patent #649,643, #852,970, #852,971, #923,058, #933,771, #s 1,060,917-1,060,922, #s 1,186,108-1,186,111.

Physical Description: The 50' one-span reinforced concrete arch bridge was built in 1913 and repaired and slightly widened (1'-6") in 1960. The widened portion of the bridge and the new parapet was built to replicate the appearance of the original elliptical arch. The steel bar reinforcement of the arch follows the intrados and extrados of the arch. Transverse reinforcement is and shear stirrups were also used in the arch, showing the use of state-of-the-art design. The spandrel walls and parapets also were reinforced with steel bars. The concrete parapets are paneled on both faces. The original luminaries that were fixed to the parapets have been removed, with new lighting fixtures placed away from the structure.

Historical and Technological Significance: The reinforced concrete arch bridge was built in 1913 by the Ferro Concrete Company of Harrisburg, PA. The firm was licensed to build arches using patented systems designed by Daniel Luten, who received patents for several types of reinforced concrete structures. This bridge and its reinforcing system, however, was designed by Alvin B. Fox, the county engineer in Union County. The design did not include the technologies that had been patented by Luten.

Luten's early patents for reinforced concrete arch bridges included the use of tying reinforcement between the skewbacks. Later patents dealt with the construction of curving wingwalls, spandrel walls, ribbed reinforcement and pavement improvements. The purpose of his inventions were "to provide an improved structure of the class referred to which shall combine a maximum of strength and efficiency with increased economy of construction".

The movement towards the lessening of dead loads on reinforced concrete arches was making possible the opening of spandrel walls and the use of ribbed arches rather than barrel designs. This was especially important on larger bridges where great quantities of material were saved building open spandrel arch bridges.

The bridge over Ambrose Brook is not significant because does not have a patented design. It was not constructed following a proprietary design, as was a common practice of the early-20th century, including several structures constructed by the Ferro Concrete Company. It has also been significantly altered by a large addition.

DESIGNER/PATENT MIDDLESEX AND SOMERSET CO. **BUILDER** ARTHUR E. SMITH, CONTRACT

SETTING / CONTEXT The bridge carries two lanes of traffic and two sidewalks across a wide stream. To the south of the bridge are several rail lines with bridges carrying them across the same stream. An abandoned building in a contractor's yard is the structure nearest the bridge. Other development is mid- to late-20th century. The bridge spans from Somerset County into Middlesex County.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span concrete elliptical deck arch bridge is the largest and best-detailed of several joint-county structures. The posts at the cutwater pier and abutments are paneled, and a denticulated cornice runs the length of the bridge. The concrete balustrade has pylons at the corners of the bridge with copper luminaries. The bridge is significant because of its state of preservation and its representation of quality joint-county bridges built on the county line prior to World War II.

INFOR MATION

Bibliography:
Middlesex County Engineer, Bridge File 2-B-235.

Physical Description: The handsome two-span concrete deck arch bridge is a well-detailed example of its type. The reinforced concrete arches are defined by paneled concrete posts at the pier and abutments that rise into classically styled pylons at the four corners of the bridge. Each is set with a handsome copper luminare that still functions. A concrete balustrade encloses the sidewalks. A denticulated cornice runs the length of the bridge below the balustrade. The entire structure is well-detailed and well preserved.

Historical and Technological Significance: The 1931 reinforced concrete arch bridge that carries Main Street over Green Brook is the most distinctive of several joint-county bridges that cross the brook (Criterion C). It is not a large bridge, but it is very ambitious in details and its proportioning and it ranks as one of the most handsome small concrete bridges in the area. It is one of the most intact examples of a common highway bridge type. The designer took full advantage of the moldable qualities of concrete, not only on normal components of bridge construction, but also using additional details, such as the pylons. It also retains its original luminaires, which add to its historic significance. The once-common lamp has become increasingly rare.

The technology of the bridge is not innovative. Reinforced concrete arch bridge were very popular in the first 30 years of the 20th century. This structure was not a pioneering feat, but made use of current proven technology. The bridge is significant because of its outstanding characterization of the joint-county bridges built during the 1920s and 1930s, using current technology of the era. It was designed by the engineering departments of Middlesex and Somerset Counties.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The boundary of significance is therefore the structure itself - including the substructure and the superstructure.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in a mixed residential and commercial neighborhood, and carries a 2-lane roadway over a small stream at the county border. An abandoned brick building which housed a pumping station is located 10' downstream from the bridge, with a new facility is located downstream of the old one. Easton Ave. is the right-of-way of the 1806 New Jersey Turnpike Company road from Easton to New Brunswick. The road was completed in 1809, but was never a commercial success.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The handsome and well-preserved skewed stone barrel-arch bridge is 35' wide with not visible signs of having been widened. The intrados is neatly coursed ashlar stone, and the opening is finished with ringstone. The beveled cap stones are original. The date stone is deteriorated, but the date is recorded in Somerset County Engineer records. The stone arch is one of the most complete early-19th century examples of its type in the area. It was built on an early turnpike road.

INFOR MATION

Bibliography:
Condit, Carl W. American Building Art, The Nineteenth Century. 1960.
Doughty, Joshua, Jr. "Early Roads in Somerset County", Somerset County Historical Quarterly, Vol. I, 1912.

Physical Description: The barrel-shaped 22'-long stone arch bridge is constructed entirely of coursed ashlar. There are no signs that the bridge has been widened. The coursed ashlar intrados are in good condition. The arches are finished with gauged ringstones, and the stone parapets have bevel-topped capstones. A limestone panel in the parapet that bore an inscription from the time of construction is weathered, obscuring the date of construction. The rest of the bridge is very well-preserved.

Historical and Technological Significance: The Easton Avenue bridge, built in 1823, is a good example of a stone arch bridge from the early turnpikes in New Jersey. The bridge is very wide in comparison to other stone arch bridges, and rises higher than many above the stream bed that is crossed. The state of preservation of the bridge is exceptional, considering the structure was completed in 1823. The spandrels as well as the structural stones are well-preserved.

The bridge is one of the oldest in area. Like most of the other late-18th and early 19th-century stone arch bridges in the state, this example was built by a turnpike company. The New Jersey Turnpike Company was chartered in 1806 to run from Easton, PA to New Brunswick. The road was completed in 1809, but it was never a financial success, and the roadway in each county was donated to that county in 1869.

DESIGNER/PATENT OFFICE OF COUNTY ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in a wooded area with scattered mixed-20th century residences. The bridge carries a two-lane collector road and two sidewalks across a small stream. The stream is dammed at the upstream face of the bridge to create a lake and a park area.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one span stringer bridge sits on concrete abutments dating to 1910. A modern concrete and aluminum railing crosses the bridge that also has beam guiderails at the curb lines. On the upstream side of the bridge is a dam fitted with manually operated flood gates. The bridge was significantly altered in 1964 (widened) and 1985 (superstructure replaced). The bridge is not evaluated as a historic structure because of the age and the common type of superstructure.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge, located in the Cranbury Historic District, carries a 2-lane street and sidewalks across a brook that has been dammed at the upstream face of the bridge to create Brainerd Lake. The period of significance for the historic district is late-18th century to early-20th century. The bridge was built during this period. While most of the structures along Main Street have been evaluated for their historical significance, the bridge was not.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Cranbury Historic District. 09/18/1980. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 23'-long brick arch bridge with rubble-coursed spandrel walls and wingwalls has gauged ringstones. The spandrel walls have utility pipe cuts, and the intrados has been covered with concrete. A low concrete buttressing system is being built along the upstream face of the retaining wall. At the upstream face of the bridge is the dam with manually operated gates. The bridge has been extensively reworked over time. The bridge is not individually eligible for listing in the National Register, but, since it was constructed within the period of significance of the Cranbury Historic District, it is thus a contributing resource under Criterion C.

INFOR MATION

Bibliography:
Cranbury Press. February 28, 1896.

Physical Description: The bridge is a 23' long elliptical brick arch bridge with rubble-coursed masonry spandrel walls and gauged ringstones. The metal pipe railings on the span and approaches appear to date to the early 20th century. The arch span is part of a mill pond dam, and the upstream arch is framed by a rounded spillway fitted with a manually operated sluice gate. The upstream approaches are ashlar-lined to create the dam, and they have been reinforced with concrete buttresses. The lower water level on the downstream face of the bridge allows a full view of the arch. The intrados of the arch is coated with gunite, an alteration completed in 1987.

Historical and Technological Significance: The brick arch bridge is a contributing element to the Cranbury Historic District, listed in the National Register of Historic Places in 1980 under Criterion A. Although it was not rated in the nomination, the bridge does contribute to the historic character of the district. According to a local newspaper entry the bridge was built in 1896, which is during the period of significance of the district that extends from the 18th century through the early 20th century.

The brick arch bridge was built in 1896 to replace a wooden bridge that had been destroyed. The bridge carries the major thoroughfare in Cranbury, and when a replacement was needed the freeholders decided that a masonry arch was the best choice for long durability and quick construction. The retaining walls were built in 1904. The is the only brick arch bridge in Middlesex County, but the bridge type, dating primarily from the second half of the 19th century, is not uncommon in the state.

Boundary Description and Justification: The bridge is within the limits of the historic district. The elements of the structure that do contribute are the span itself, the retaining (wing) walls and the railing of the structure.

SETTING / CONTEXT The bridge is located in a mid to late 20th century residential and commercial area, and carries a 2-lane road with 2 sidewalks over a single track of ConRail's Sayreville Secondary. The line was built in 1890 by the Raritan River Railroad as an extension of its line from South Amboy to Washington (4 mi.) built in 1888. The R.R. RR built a few branches during these years, but they do not remain in service. Conrail obtained the line in 1980 and still uses it for freight.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span stringer bridge sits on a concrete substructure of abutments and piers with arched struts. The exposed bottom flanges reveal that each longitudinal member is composed of paired I-beam stringers. This is the only bridge surveyed in Middlesex County that has a coupled stringer arrangement, but the basic bridge type is common. Chain-link fencing lines the sidewalks at both faces of the bridge. The bridge is not technologically or historically distinguished.

SETTING / CONTEXT The bridge spans the abandoned Perth Amboy-South Plainfield rail line. It carries a narrow two-lane road from a mid to late 20th century industrial area to a mid-20th century residential area. The rail line was built in the 1870s as the Lehigh Valley Railroad's main line to New York harbor. It became a branch when they extended the line from South Plainfield to Jersey City in the 1880s. Conrail took possession of the Lehigh Valley RR in 1976.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span steel girder bridge with a "broken-back" profile sits on timber pile bents and abutments. The steel floorbeams are suspended from the girders, supporting timber stringers and a timber plank deck wide enough for only one vehicle. The added pipe railing is welded to the top flange of the girders, with chain-link fencing against the rail. The bridge is relatively early, but it is not technologically or historically distinguished.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Bridge was Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The riveted Warren pony truss bridge sits on caisson-like concrete-filled piers with metal sheet-pile back walls. It is additionally supported midspan by a timber bent. Because the trusses work in conjunction with a stringer approach span, it is possible that they were moved to this crossing at an unknown date. The bridge is technologically significant in that the trusses are well preserved and that it is the only remaining pony truss bridge in the county.

INFORMATION

Bibliography:
Condit, Carl W. American Building Art, The Twentieth Century, 1961.
Waddell, J.A.L. Bridge Engineering, 1925.
Middlesex County Engineer, Bridge File 5-B-055.

Physical Description: The 2-span bridge is composed of one stringer span and one riveted Warren pony truss span. The truss is supported on caisson-like concrete piers in steel casing. An additional timber bent supports the truss below a mid-span floor beam. The stringer span is supported on a floor beam that rests on the piers at the west end of the truss span and by a steel bent built of rolled sections at the west abutment. Metal sheet-piling retains the fill behind the structural members at each abutment. The virtually unaltered truss members are built-up using angle sections and lacing or batten plates. The top chord has a solid cover plate. Rolled floor beams and stringers support the timber deck.

Historical and Technological Significance: The 1910 Rue Road bridge is the only remaining truss bridge in Middlesex County, and as such is technologically significant as the sole representative of an important and once-common bridge type (Criterion C). The riveted Warren pony truss is the most common bridge type for early-20th century short-span crossings. Rue Road is a well-preserved example of the influential Warren pony truss. Also of technological significance are the caisson-like piers that support the truss. They are not a common detail with only about half a dozen examples identified on highway bridges throughout the state (2 in Morris County; 1401021, 1400976). They appear to have been an expedient solution to erecting a pier without erecting a coffer dam.

Because of the stringer approach span, the truss bridge seems too short for the crossing. It is possible that the truss was originally at a different location. A common practice of the early-20th century was the county use of bridges which the state was replacing in favor of larger structures. Documented cases of the practice exist in Mercer County where the ca. 1895 truss bridge at Groveville-Allentown Road (1100028) was moved from Pennington and the Iron Bridge Road span (1106704), a pony truss with a stringer approach span (a similar arrangement to the Rue Road bridge) was also relocated. There is no information in the county engineer's records to document the history of the span.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The boundary of significance is therefore the structure itself - substructure as well as superstructure.

DESIGNER/PATENT OTIS R. SEAMAN, CO. ENG. **BUILDER** FRIEBOTT BROTHERS

SETTING / CONTEXT The two-lane bridge spans the Bucks Mill Pond spillway. The bridge's single sidewalk is carried separately from the bridge on timber stringers. To the north is a large waterwheel, tailrace, and stone foundation, the only remnants of Bucks Mill, a 19th-century gristmill that caught fire and was destroyed (post-1954). The surrounding neighborhood is now residential with modern subdevelopments and a scattering of older farmhouses.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span nail-laminated timber slab bridge has concrete abutments and timber pile bent pier with cross bracing. Timber rails have been replaced by beam guide rails. According to county records in 1948 the adjacent timber dam bulkhead was rebuilt, and in 1961 the concrete spillway floor repoured. The bridge is one of at least six surviving 1940s timber slab bridges in Monmouth County. The bridge is not historically or technologically distinguished.

SETTING / CONTEXT The 2-lane bridge spans Jumping Brook on the northern border of Shark River County Park. To the south of the bridge is woodland, and to the east the Shark River County Golf Course. West of the bridge is a modern office building, and a residential subdevelopment (c.1960-80).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1925 steel stringer bridge with steel bents and lattice railings has been rebuilt twice. In 1940 concrete footings, longitudinal bracing between the piers, and 9 I-beam stringers in addition to the original 6 stringers were added. In 1954 beam guide rails and a French drain were added, and a secondary system of steel piers changed the bridge from 11 spans to 22 spans. The highly altered bridge is not historically or technologically distinguished.

SETTING / CONTEXT The 2-lane bridge with single sidewalk spans Glimmer Glass, a navigable tidal inlet of the Manasquan River. The bridge is located in a salt marsh surrounded by what historically was a seasonal community of small cottages. Many of the cottages have been enlarged and/or converted to year round houses. Large, modern houses have also been added, often replacing the original cottages. The area does not have historic district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The rolling counterweight single-leaf bascule bridge with a deck girder movable leaf is the only example of the late-19th century bridge type in the state and possibly the whole country. The undocumented bridge represents a little-used technology that was developed prior to 1895. It was used in New Jersey by railroads and over canals. Although the Glimmer Glass bridge has been modernized, it still operates in the original manner and is thus historically and technologically significant.

INFOR MATION

Fraser, Donald J. "Movable Span Bridges in New South Wales Prior to 1915." Multi-disciplinary Engineering Transactions. 1985.
Hool, George and Kinne, W.S. Movable and Long-Span Steel Bridges. New York: McGraw Hill Book Company, 1943."The Michigan Avenue Bascule Bridge Buffalo," The Engineering Record, Vol.66 (Aug. 21, 1897), pp. 246-247.
Perkons, George (Mechanical Engineer with A.G. Lichtenstein & Associates). Personal interview with Mary E. McCahon, 1/19/1993.
Waddell, J.A.L. Bridge Engineering. New York: John Wiley and Sons, 1925.

Physical Description: The 17-span bridge is composed of 16 timber stringer spans supported on braced timber pile bents and a 31'-long cable lift bascule rolling counterweight movable span. The single-leaf movable span is a deck girder with an open steel grid deck installed in 1962. A cable attached to each side of the toe end of the movable leaf passes over a single-track sheave atop the braced timber tower columns with braced curved tracks on the side opposite the movable leaf. The opposite end of the cable is attached to a connecting hanger that joins the shafts of the rolling counterweights positioned in series on the track. The two topmost metal counterweights have a solid center guide while the last one has disk guides. The track has built up wood end stops. The tower columns are braced with wood struts on the sides and wire rope stays on the back. The toe lock is manual. The bridge is controlled from an operators house on the upstream side. An electric motor mounted atop the upstream tower column brace engages the drive shaft to turn the sheaves which cause the counterweights to start moving down the track. The motor reverses the action to close the bridge. The operators house, like many elements of the bridge, has been upgraded over the years, but its function and profile are original.

Historical and Technological Significance: The ca. 1898 cable lift bascule with rolling counterweights bridge is technologically and historically significant as the only example of its type in New Jersey (criterion C). It may also be the only example in the eastern half of the United States (Perkons). When the design was developed and by whom was not identified, but the 1896 Scientific American article describing the Erie Railroad's recently completed example on its main line over Berry's Creek near Rutherford, New Jersey (non-extant) states that " although the principle upon which the bridge is constructed is not entirely new, the Berry Creek bridge is the first application of this system of counter weighting for a structure of this magnitude." The principle is to use a curved track and rolling counterweights where the work expended in raising the leaf is equal to the energy released by the falling counterweight. The toe end of the movable span is linked by cables to cylindrical rolling counterweights. The connecting cable passes over a tower column with a curved track. Moving the counterweights along the curved track thus raises or lowers the bridge.

It is known that in addition to erecting the rolling counterweight span at Berry Creek in 1896, the Erie Railroad used the technology to carry its Greenwood Lake branch over the Morris Canal, and that the Central Railroad of New Jersey built a similar bridge over the Morris Canal guard lock at Dover (Morris County). The canal bridges are recorded in the abundant photo documentation of the canal. Perhaps the best-known of the cable-lift rolling counterweight bridges was the 1897 Michigan Avenue bridge over the Buffalo River at Buffalo. A double-leaf span, it was designed and fabricated by the Wisconsin Bridge and Iron Company of Milwaukee. The steam-powered bridge was a more complicated design than the Glimmer Glass example, but the operating principle was the same. Another example was built in 1898 by the Canton Bridge Company (fabricator) and Dean & Westbrook (contractor) over Coney Island Creek between Brooklyn and Queens.

The bridge type was also built in Australia and is known there as the "American" bridge. It was apparently introduced in that country prior to 1903, and the use of the design is noted as marking the shift from using English to American movable bridge technology. At least three examples survive, and one was built as late as 1922 (Fraser).

No original records or plans for the Glimmer Glass span have been retained in the county engineer's files. It is dated ca. 1898 based on its design. The bridge has been rebuilt several times. The wood tower column and track were redone in 1957 and 1971, and the steel grid deck on the ca. 1950 deck girder movable span was installed in 1962. The significance of the structure is derived from the fact that it maintains integrity of original design.

Boundary Description and Justification: The bridge is evaluated as individually distinguished, and the significant boundary is limited to the bridge itself. The area surrounding the bridge does not possess the integrity needed to be evaluated as a potential historic district.

SETTING / CONTEXT The single-lane bridge spans Yellow Brook in a lightly developed residential area interspersed with farmland and nurseries. Next to the bridge is a small, wooded municipal park.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The riveted 4-panel Warren pony truss bridge has been significantly altered and no longer functions as a truss bridge. In 1944 the bridge was underpinned with stringers on braced timber piles placed at the floorbeams. Sections of the trusses are holed through or missing. Original plans for the bridge do not exist with the county engineer, but the truss style dates from circa 1910. The altered and deteriorated bridge is not historically nor technologically noteworthy.

INFOR MATION

Bibliography:
Monmouth County Engineer. Bridge Plans for Bridge No. A-23. 1944.

Physical Description: The bridge is a 4-panel rivet-connected Warren pony truss. The upper chords and inclined end posts are channels with cover plates and lacing. The lower chords and diagonals are angles with battens. The flooring system consists of rolled I beam floor beams, timber stringers, and a plank deck. The truss bearings rest on concrete-filled riveted cylindrical steel caisson-like columns with stone back walls and timber sheet pile bulkheads. The cassison-like columns have lost section. The bridge has been underpinned at each floor beam and abutment with braced timber piles. The original railings have been removed, and beam guide rails have been added. Portions of the lower chord are missing. The bridge no longer functions as a truss but as a 4-span timber stringer bridge.

Historical and Technological Significance: The undocumented ca. 1910 Warren pony truss bridge has lost its integrity of design as a result of modifications and deterioration to both the superstructure and the substructure. A search of the county engineer's records offered no information on the bridge's builder or date of construction. Stylistically the span dates from ca. 1910. Plans indicate that major repairs occurred in 1944 when the truss was underpinned, a truss leg was repaired and welded, a new deck constructed, and the abutments repointed. The Warren pony truss was a popular highway bridge type in the first decades of the 20th century. A more complete example is the multi-span Locust Road over Claypit Creek (130MT21, Middletown Township).

To the east of the bridge are townhouses and a restaurant (c.1970-80). To the west are office buildings and a municipal rescue station (c.1970-80). Downstream from the bridge is a large water main resting on timber piles.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY In 1923 the bridge was built as a 20'-wide encased steel stringer with pipe railings and a single concrete sidewalk. The bridge's concrete abutments were battered to meet a previous bridge's brick and masonry abutments. In 1951 the bridge was widened to 27', the existing I-beams reset, and a new beam added. The original sidewalk was removed and the timber stringer sidewalk added. Steel stringers are a common bridge type, and the bridge is not historically or technologically distinguished.

 # SPANS 1 **LENGTH** 61 ft **WIDTH** 30 ft

CONSTRUCTION DT 1928 **ALTERATION DT** Unknown **SOURCE** PLAQUE

DESIGNER/PATENT CENTRAL RAILROAD OF NEW JERSEY **BUILDER** BETHLEHEM STEEL COMPANY

SETTING / CONTEXT The two-lane bridge with single sidewalk spans a single track of New Jersey Transit's Southern Division, the former Central Railroad of New Jersey. The right-of-way was originally developed in the late-1850s by the Delaware and Raritan Bay Railroad, and later merged with the New Jersey Southern Railway (c.1870), a company owned by the CRR of NJ. The current surroundings are suburban with an apartment complex to the east, and the Fort Monmouth Country Club to the west.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1-span steel thru girder with floor beams bridge has a cantilevered sidewalk with a metal railing. The concrete abutments have been widened, and some of the stringers are skewed to accommodate realignment and widening of the bridge and roadway or relocation of the superstructure to this site. No records were located at the county or state offices. It is a common overpass bridge type, and it is not historically or technologically distinguished.

CONSTRUCTION DT 1909 **ALTERATION DT** **SOURCE** COUNTY ENGINEER

DESIGNER/PATENT UNKNOWN **BUILDER** NELSON-MERYDITH

SETTING / CONTEXT The 2-lane bridge spans a small creek in a suburban area south of Freehold Borough near the intersection of US 9 and CR 524. Adjacent to the bridge is a field belonging to the Rutgers University Soils and Crops Research Center. To the west is a shopping center and suburban development (post-1960).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span reinforced-concrete arch has paneled parapets. Beam guide rails and utility pipes have been added. The intrados is spalling exposing the reinforcing. Spalling is evident all over the structure. The 1909 bridge is an early example of its type in the county, but it is technologically representative of numerous concrete arches built in the state in the first decades of the 20th century. The deterioration mars its integrity and limits the significance of the span.

SETTING / CONTEXT The 2-lane bridge with sidewalks spans Sunset Lake, a 5-block long lake and surrounding park in Asbury Park, one of New Jersey's most famous beach resorts. The park is a central feature of the city's layout, and the bridge is situated with a view of the historic beachfront hotels and convention hall. The surrounding residential neighborhood dates from c.1870-1930 with many unaltered permanent homes and summer cottages. The neighborhood possesses historic district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Bridge was Not Individually Eligible. Agreed Potential shore resort Historic District. Contributed.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The Grand Avenue bridge is a three-span deck girder with floorbeams and concrete abutments and piers. In 1922 the bridge was constructed with pipe railings, but in 1923 the bridge was rebuilt with paneled concrete parapets inset with mosaics and topped by decorative lanterns and light standards. The bridge is a representative example of period technology and is not individually notable, but it would contribute to the potential historic district because of its date of construction.

INFOR MATION

Bibliography:
History of Monmouth County, New Jersey, 1664-1920. New York: Lewis Historical Publishing Co., 1922. pp. 405-416.
Kobbe, Gustav. The New Jersey Coast and Pines. 1889; reprint ed., New York: Walking News, 1982. pp. 45-46.
Monmouth County Engineer. Bridge File: N-14.

Physical Description: The three-span multi deck girder with floor beams bridge is composed of three built-up steel plate deck girders with concrete deck and cantilevered sidewalk per span. The bridge abutments, wingwalls, and piers are reinforced concrete as is the bridge deck. The paneled concrete parapets have tile mosaics at center span that read "Sunset Lake and Park." Expansion joints have been cut in the parapets. Original street lighting has been removed and replaced with modern highway lighting. A nicely detailed concrete arch span with staircases is located at the southwest abutment connecting the upstream side sidewalk with a small manmade island in the lake. The small arched structure is finished with brick posts, and accenting and decorative iron railings.

Historical and Technological Significance: The 1922-23 Grand Avenue Bridge in Asbury Park City is not individually distinguished, but it is located within the boundaries of a potential historic district, and would be eligible under criterion A for its association with the events and broad patterns of history associated with the potential historic district. It was built within the period of significance of the district, which extends through at least 1940. The bridge is in Sunset Park, a manmade lake and surrounding green space, one block wide and eight blocks long oriented on the east/west axis. At the eastern, or beach, end of the park are the architecturally-impressive Paramount Theater and Convention Hall (c.1920), board walk, and early-20th century multi-story resort hotels. The park is bordered on the other sides by well-preserved and architecturally noteworthy late-19th and early-20th century seasonal and year-round residences that developed around the lake, a civic amenity that is historically the focal point of this portion of the community.

In the early 1870s Asbury Park was founded as an outgrowth of the Ocean Grove Camp Meeting Association. The New York and Long Branch Railroad extended its lines south in 1876, and Asbury Park quickly transformed into one of the most well known and popular resorts on the Shore with a boardwalk, bath house and hotels. The seasonally-oriented city was centrally planned and was noted for its modern conveniences including broad avenues, "running at right angles to the sea, from one to two hundred feet wide" (History of Monmouth County, p. 406). Sunset Lake and park were central features in the layout of the resort town, and they were designed to provide recreation and an east-west promenade. A boat house was located at the southern end of the small island accessed by the arch bridge off the Grand Avenue Bridge.

In 1922 the Grand Avenue bridge over Sunset Lake was constructed as part of the completion of a county highway project. Prior to 1922 the only highway bridges across the lake had been at Bond and Emory Streets. The deck girder was originally built with pipe railings and creosoted plank sidewalks, but in 1923 the railings were replaced with the more distinguished concrete parapets with mosaics and street lighting. The new railings were more in line with contemporary ideas of an appropriate style for municipal parks and public spaces. The bridge is a representative example of early-20th century plate girder bridge technology.

With the exception of removal of the original lighting, the bridge appears basically unchanged, but there is some spalling. In 1975 the expansion joints were cut in the parapets on both sides of the bridge.

Boundary Description and Justification: The bridge is located in a potential National Register historic district with a period of significance from ca. 1875-at least 1940. Since the bridge was built as a civic amenity in a planned resort community and was built in 1922-23, it is evaluated as a contributing resource to the potential historic district. The area surrounding the bridge would be included in the potential historic district. The span is not individually significant, and its evaluation is based on the area in which it is located being determined a historic district.

CONSTRUCTION DT 1924 **ALTERATION DT** **SOURCE** PLAQUE
DESIGNER/PATENT GEORGE K. ALLEN, JR., CO. ENG. **BUILDER** DOVER BOILER WORKS

SETTING / CONTEXT The 2-lane bridge with two sidewalks spans picturesque Deal Lake between Asbury Park City (east) and Wanamassa village in Ocean Township to the west. Deal Lake is a large, manmade water feature created in the late-19th century as part of the development of the beach resorts. On either side adjacent to the bridge are architecturally significant 1880-1929 residential areas in a good state of preservation. They appear to have National Register historic district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Not Individually Eligible. Potential Deal Lake Historic District. Contributing.
CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 5-span encased haunched deck girder with floorbeams bridge has concrete balustrades, paneled parapets on the eastern curved approach, and concrete abutments and piers with struts. Portions of the balustrades have been replaced with parapets. Because of the alterations and the fact that the builder is more commonly associated with earlier metal truss bridges, the bridge is not individually eligible for listing in the National Register. However, the bridge is located within a lakefront community which includes portions of both Asbury Park City and Wanamassa, and which comprises a potential historic district. Current information suggests the district would be eligible under Criteria A and C, and the period of significance would be from ca 1880 to 1929. The bridge would be a contributing element.

INFOR MATION

Bibliography:
History of Monmouth County, New Jersey 1664-1920. New York: Lewis Historical Publishing Co., 1922. pp. 465-472.
Kobbe, Gustav. The New Jersey Coast and Pines, 1889; reprint ed., New York: Walking News, 1982. p.45.
Monmouth County Engineer. Bridge Plans for Bridge Number O-10. 1924.
Ocean Township. The Township of Ocean Commemorative Book. 1949.
The WPA Guide to 1930s New Jersey. 1939; reprint ed., New Brunswick: Rutgers University Press, 1986. p. 682.

Physical Description: The bridge is a five span encased deck girder with built-up floor beams. The 55-foot long deck girders are haunched ranging in depth from 5 foot 6-1/2 inches depth at the bearings to 4 foot 6-1/2 inches depth at center span. The reinforced concrete abutments and piers with cross beams are founded on timber pile foundations. The cantilevered sidewalks have concrete balustrades. Original octagonal luminaires on pyramidal concrete standards have been removed and replaced with modern metal lighting. A few concrete balustrade panels have been replaced with solid concrete parapets.

Historical and Technological Significance: The 1924 Sunset Avenue bridge is not individually distinguished, but it is located within the boundaries of a potential historic district with Deal Lake as the focus (criterion C). The bridge spans an arm of Deal Lake, a manmade water feature that forms the border between Asbury Park City to the east and Wanamassa in Ocean Township to the west. Deal Lake extends nearly two miles inland from the ocean and is bordered by many architecturally noteworthy and well preserved late-19th and early-20th century homes with many oriented toward the lake. They comprise an impressive assemblage of buildings with good architectural integrity and few modern intrusions. The Wanamassa village area east of the Sunset Avenue bridge is a particularly well-preserved enclave of Craftsman bungalows. The bridge is contemporaneous with the residences and would be considered a contributing structure to a potential historic district. The lake borders the municipal boundaries of Allenhurst Borough, Asbury Park City, Deal Borough, Interlaken Borough, Loch Arbour Borough, and Ocean Township.

Deal Lake was originally an inlet of the ocean until it was diked sometime in the 18th century as a means of preserving fresh water for nearby fishermen, farmers, and a small tourist trade. In 1878 the New York & Long Branch Railroad extended its line south from Long Branch, and the dike was improved. Investors began to purchase land adjoining the lake in anticipation of the development of resort communities. The village of Loch Arbour, at the lake's northeastern end, was the first to be laid out in house lots, but growth around Deal Lake was not rapid until the first decade of the twentieth century. Development proceeded under the direction of a number of land companies, generally corresponding to present-day corporate boundaries. The companies advertised "thriving villages" for "men of wealth and position." The village of Wanamassa at the bridge's western approach began development in the 1890s as a YMCA camp meeting and revival community. An auditorium and running track were constructed, and house lots were sold. For a while the housing market slumped, and the property was purchased by Nathan J. Taylor. Wanamassa acquired a reputation as a "high-class bungalow colony." Numerous summer homes in the late-Victorian, Craftsman, and Colonial Revival styles were constructed. The historic period of development ended in 1929 with the Great Depression.

In 1924 the Sunset Avenue bridge was constructed across Sunset Lake. The western portions of the lake were some of the last of the lake front areas to be developed. The bridge was part of the realignment of Sunset Avenue. Its design, with concrete balustrades and handsome luminaires, was in keeping with contemporary ideas of bridge aesthetics. The span is a representative example of period deck girder bridge technology, and is one of two 1920s bridges spanning Deal Lake (Monmouth Road, 1929, 1300O13, Interlaken Borough) that contribute to the potential historic district.

Boundary Description and Justification: The bridge is located within a potential National Register-eligible historic district with a period of significance from ca. 1880 through 1929. If the district were created, the bridge, its superstructure and substructure, would lie within the district's boundaries and would be a contributing resource because it was built within the period of significance.

SETTING / CONTEXT The two-lane bridge with two sidewalks spans Deal Lake, a manmade water feature that forms the border between Allenhurst Borough to the east, and West Allenhurst in Ocean Township to the west. The lake was created in the late-19th century as part of the development of the beach resort towns. On either side of the bridge are architecturally significant residential areas (1880-1929) that possess National Register historic district potential.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY In 1941 the bridge was built as a 17-span timber stringer with timber pile bents, and timber deck and railings. In 1977 it was substantially rebuilt as a 20-span timber stringer with timber pile bents, steel railings, and corrugated pan deck with an asphalt wearing surface. Little or no original bridge fabric remains, and the bridge is essentially an all modern structure. It would not contribute to the potential historic district based on its age.

SETTING / CONTEXT The 2-lane bridge with two sidewalks spans Deal Lake, a large manmade water feature that forms the border between Interlaken Borough to the south and West Allenhurst in Ocean Township to the north. The lake was created in the late-19th century as part of the development of the towns. The late-19th and early-20th century residential areas on both sides of the lake are architecturally distinguished and well preserved. They possess historic district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Not Individually Eligible. Potential Deal Lake Historic District. Contributed.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 4-span encased thru girder with floorbeams bridge has cantilevered sidewalks with balustrades that originally had luminaries and pipe railings on top of the girder. In 1963 the piers were reconstructed and changed from a rounded to a faceted profile. The bridge is representative of period technology and was constructed contemporaneously with the surrounding 1880-1929 resort community residences. While the bridge is not individually eligible for listing in the National Register of Historic Places, the bridge is located within a lakefront community which includes portions of both Asbury Park City and Wanamassa, and which comprises a potential historic district. Current information suggests the district would be eligible under Criteria A and C, and the period of significance would be from ca 1880 to 1929. The bridge would be a contributing element.

INFORMATION

Bibliography:

History of Monmouth County, New Jersey, 1664-1920. New York: Lewis Historical Publishing Co., 1922. pp. 465-472.
Kobbe, Gustav. The New Jersey Coast and Pines, 1889; reprint ed., New York: Walking News, 1982. p. 45.
Monmouth County Engineer. Bridge File: O-10.
WPA Guide to 1930s New Jersey. 1939; reprint ed., New Brunswick: Rutgers University Press, 1986. p. 682.

Physical Description: The bridge is a four-span concrete-encased steel thru girder with floor beams and a concrete deck. Each span has two five-foot depth girders with paneled fascia. The abutments and piers are reinforced concrete on pile foundations. The cantilevered sidewalks have standard-design concrete balustrades. Original lighting has been removed and modern metal lamps have been added.

Historical and Technological Significance: The 1929 Monmouth Road bridge is not individually distinguished, but it is located within the boundaries of the potential National Register historic district surrounding Deal Lake (criterion C). The bridge spans an arm of Deal Lake, a manmade water feature that forms the border between Interlaken Borough to the south and West Allenhurst in Ocean Township to the north. Deal Lake extends nearly two miles inland from the ocean and is bordered by many architecturally distinguished late-19th and early-20th century houses, some of which are oriented toward the lake. They form an impressive assemblage of buildings with good architectural integrity and few intrusions. The Interlaken Borough and West Allenhurst area has many well-preserved Colonial Revival style homes, most of which date from c.1910-1930. The bridge is contemporaneous with the residences and would be a contributing resource to a potential historic district. The lake borders the municipal boundaries of Allenhurst Borough, Asbury Park City, Deal Borough, Interlaken Borough, Loch Arbour Borough, and Ocean Township.

Deal Lake was originally an inlet of the ocean until it was diked sometime in the 18th century as a means of preserving fresh water for nearby fishermen, farmers, and a small tourist trade. In 1878 the New York & Long Branch Railroad extended its line south from Long Branch, and the dike was improved. Investors began to purchase land adjoining the lake in anticipation of the development of resort communities. The village of Loch Arbour, at the lake's northeastern end, was the first to be laid out in house lots, but growth around the lake was not rapid until the first decade of the twentieth century. Development proceeded under the direction of a number of land companies, generally corresponding to present-day corporate boundaries. In 1889 a group of New York City investors bought land in the area of Interlaken with the intention of building a resort; in 1896 the Coast Land Company purchased the tract of land incorporating Allenhurst; and, beginning in the 1900s, the Continental Investment Company began to sell house lots in Deal. The companies advertised "thriving villages" for "men of wealth and position." Numerous summer homes in the late-Victorian, Craftsman, and Colonial Revival styles were constructed. The historic period of development ended with the Second World War.

In 1929 the Monmouth Road bridge was constructed across Deal Lake. The western portions were some of the last of the lake front areas to be developed. The design of the bridge with concrete balustrades and handsome luminaires was in keeping with contemporary ideas of bridge aesthetics. The bridge is a representative example of period thru girder bridge technology, and is one of three 1920s bridges spanning Deal Lake including Sunset Avenue (1924, 1300O10, Asbury Park City) and Main Street (1925, 1300O11, Interlaken Borough). 1300O11 was evaluated as not significant because it is not located in a potential historic district.

Boundary Description and Justification: The bridge is located in a potential Deal Lake Historic District with a period of significance from 1880 through 1929. Thus it and its surroundings are evaluated as significant. The bridge would be within the district's boundaries and would be considered a contributing resource based on its date of construction.

SETTING / CONTEXT The two-lane bridge spans Pine Brook within the Tinton Falls Historic District (c.1700-1900), a historic crossroads village on both sides of the creek. South of the bridge is a congested intersection with several modern intrusions, and historic grist mill, converted to a restaurant. The 18th and 19th-century homes north of the bridge on Tinton Avenue have retained some of their historic character, but there are many intrusions and alterations to buildings in the district.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. May contribute. Listed. Tinton Falls Historic District. 11/10/1977. Not Rated.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 5-panel pin-connected Pratt pony truss with vertical end posts has been heavily altered and no longer functions as a truss. It is rusted and portions of the lower chords and diagonals are lost. In 1953 the bridge was underpinned with steel stringers on concrete piers, and a laminated deck added. The deteriorated bridge has lost its integrity of design and is too altered to contribute to the historic district.

INFOR MATION

Bibliography:
Monmouth County Engineer. Bridge File: S-13.
Office of New Jersey Heritage. National Register File: Monmouth County; Tinton Falls Historic District, 1977.

Physical Description: The truss leg bedstead bridge is a four-panel pin-connected Pratt pony truss. The upper chords and vertical end posts are built-up box beams with cover plates and lacing. The lower chords and verticals are angles with battens. The diagonals are eye bars, and the counters are round rod stock with turnbuckles. The built-up floor beams are placed above the lower chords and are connected to the verticals by rivets. The deck is a nail-laminated timber deck. It is not known whether the standard rolled members are steel or iron; the presumed age of the bridge suggests that wrought iron construction is likely. A single wood plank sidewalk with wood railing is cantilevered off the bridge's upstream side. The bridge has a lattice railing on the downstream side. The bridge bearings rest on riveted cylindrical metal caisson-like piers.

Numerous alterations have been made to the truss. All but one of the piers and bearings have been encased in concrete. The bridge originally had stone abutments, but these have been covered over and strengthened with concrete. The span is underpinned with concrete battered columns at the second and fourth panel points. Steel I-beams support the truss floor beams of the interior panels. The bridge no longer functions as a truss, portions of the lower chord are missing, the downstream truss is severely racked, and the bridge members are heavily rusted. The live load is carried by the stress-laminated timber deck and the system of underpinning. Utility pipes are supported by welded brackets off the truss's upstream side. Another utility pipe passes through holes cut in the floor beams on the downstream side. Beam guide rails have been added.

Historical and Technological Significance: The ca. 1890 Pratt truss pony truss lacks integrity because of alterations and deterioration. The alterations and deterioration have changed the bridge so much that, despite its uncommon design, it has lost its historical and technological significance. It is located within the boundaries of the National Register-listed Tinton Falls Historic District, an 18th- and 19th-century village with nine contributing residences, an early grist mill, and a number of archaeological and historical points of interest. The district lies on both sides of the Pine Brook, the feature the bridge crosses, but the bridge was not rated in the 1977 nomination. In recent years modern intrusions and alterations have compromised the historic character of a number of the sites on the southern side of the district. Not the least of the intrusions is increased traffic congestion and convenience stores at the intersection of Tinton Falls Road and Water Street immediately south of the bridge.

The bridge was built within the district's stated period of significance, but its alterations and loss of design integrity are so significant that it is non-functional as a bridge with the trusses now little more than a decorative railing for the underpinning and laminated deck that support the live loads. The original truss bridge is too altered to be evaluated as a contributing resource to the historic district.

The county engineer's records offered no data on the bridge's builder or date of construction. Stylistically the truss dates from circa 1890. The lack of documentation further limits the bridge's technological and historical significance. In 1953 the truss was underpinned, the sidewalk added, the concrete abutments built to strengthen the original stone abutments, and the nail-laminated deck constructed.

SETTING / CONTEXT The two-lane bridge with single sidewalk spans the Swimming River west of downtown Red Bank. Next to the bridge's southeast abutment is a small boat rental. A multi-span deck girder bridge carries New Jersey Transit's North Coast Line across the river downstream. The neighborhood to the west is undistinguished suburban residential and commercial.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 6-span thru girder with floor beams bridge has concrete abutments circular column piers with struts and a wood-plank cantilevered sidewalk with pipe railing. It was constructed by the American Bridge Co. in 1920 to replace a 10 span bowstring pony truss bridge. In 1954 the steel grid deck replaced a wood deck, and steel spacers were placed on top of the existing stringers. The bridge is a representative example of a common type, and is not historically or technologically distinguished.

DESIGNER/PATENT ASH HOWARD NEEDLES & TAMMEN **BUILDER** FRED T. LEY & COMPANY

SETTING / CONTEXT The two-lane bridge with single sidewalk spans the almost 1/2-mile wide Navesink River between Locust Point in Middletown Township and Rumson Borough. The setting is picturesque with residential communities on both banks of the navigable river. At Locust Point are some 19th-century estate homes interspersed with new construction. Next to the Rumson bridge approaches are a modern marina and restaurant.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge's main span is a double-leaf haunched deck girder bascule, and the approach spans are 16 haunched deck girder spans and 40 T-beam spans. The WPA-funded project is historically and technologically noteworthy. Its design details demonstrate careful attention to style and proportion including Moderne-style steel railings and operator houses. The largely original machinery is an early example of enclosed gearing. The bridge is a significant example of its type.

INFOR MATION

Bibliography:
Brown, Kathi Ann. Diversity by Design: Celebrating 75 Years of Howard Needles Tammen & Bergendorff, 1914-1989. New York: 989.
Monmouth County Engineer. Bridge File: S-31.
Monmouth County Historical Association. Vertical File: Bridges 1891 to 1940.
U. S. Patent Office. "L. R. Ash, et. al., Bascule Bridge Patent Number 1,633,565." 28 June 1927.

Physical Description: The well-preserved Oceanic Bridge is 57 spans and measures over 2700', or slightly more than a half a mile in length. To the north and south of the bascule span are 8 haunched deck girder with floor beam approach spans and 20 reinforced concrete T-beam spans. The main span is a 98'-span double-leaf haunched deck girder simple trunnion bascule with fixed counterweights. The substructure consists of concrete abutments, concrete column bents with concrete caps for the T-beam spans, and concrete piers with lateral bracing for the deck girder spans.

The double-leaf bascule span is operated by means of pinions which engage racks attached to the main girders. The pinions are operated through a train of gears connected to electric motors with back up gasoline engines. The bascule retains all of its original enclosed primary and secondary reducer gears. The bascule's electrically operated brakes appear to be modern replacements. The tail end of each bascule leaf carries a fixed concrete counterweight. The deck girder bascule has rolled I-beam floor beams and stringers with a modern steel grid deck. The toe locks are the original electrically operated jaw locks. In addition to the original manually operated metal crash barriers, automatic barriers and signals have been added. The bridge appears to retain its original operator's control panel and electrical systems.

The bridge is distinguished by its Moderne-style detailing. The two concrete operator's houses have a semi-circular profile with banded or ribbons windows and bold vertically-scored pylons with segmental tops flanking the entry doors. The manually-operated steel plate girder crash gates have circular cutouts, and bracketed concrete hinge posts. The concrete and metal railings on the approach spans and the similarly styled metal railings on the bascule span have bulbous "streamline" profiles.

Historical and Technological Significance. The 1939 Oceanic Bridge is one of the most architectonic and technologically distinguished 20th-century double leaf bascule bridges in New Jersey. It is eligible under criterion C of the National Register for embodying the distinctive characteristics of a type, period, and method of construction. The bascule was designed by the well-known firm of Ash-Howard-Needles & Tammen, the most prolific designers of movable span bridges in the late 1920s and 1930s in New Jersey. It makes use of the firm's patented trunnion supports. The bascule is exceptionally well preserved, and it retains almost all of its original operating machinery, gears, and equipment. It is one of the earliest documented uses of enclosed primary and reducer gears in New Jersey. The bridge's Moderne styling and well-proportioned design lend it a distinction not shared by many other bridges in the state.

The first bridge from Locust Point to Rumson across the Navesink River was constructed in 1891. It was a thru truss swing span with Warren pony truss and steel stringer approach spans on metal pilings fabricated by Dean and Westbrook of New York City. By the mid-1930s that bridge had fallen into poor condition, and local residents and municipalities began to look into the possibility of replacing the bridge. In 1937 the Rumson Borough Council and the Monmouth County Freeholders passed recommendations for applications to the State Highway Department and federal Public Works Administration, a source of funding, for a new bridge. In June 1938 the Federal Works Agency, Public Works Administration granted the county's application and agreed to pay 45 per cent of the estimated one million dollar cost of the new bridge. The firm of Ash-Howard-Needles and Tammen of New York and Kansas City acted as consulting engineers for the movable span, and the primary contractor was Fred T. Ley and Company. Lionel W. Lancaster performed the duties of resident engineer, and state bridge engineer Morris Goodkind consulted on the project. The bridge was completed in early 1940 and was representative of state-of-the-art bascule bridge technology and period aesthetics.

Ash-Howard-Needles and Tammen was one of the nation's leading designers of movable spans. The firm's principal members began their careers in the 1890s and 1900s under the tutelage of bridge engineer J. A. L. Waddell and his partner John Lyle Harrington. In 1914 Waddell and Harrington dissolved their partnership, and a new firm, Harrington, Howard, and Ash, was formed; in 1928 the partnership

A. G. Lichtenstein & Associates, Inc. performed initial survery.
NJDOT updated data 03-01-2001.
Correction Updates Etc should be sent to
Correspondence.Unit@DOT.State.NJ.US
November 12, 2002

became Ash-Howard-Needles and Tammen. From 1914 to 1928 the firm designed more than 45 vertical lift bridges, 13 bascule bridges, and six rolling bascule bridges, including a series of 18 movable bridges across the Welland Canal in Ontario, Canada. During the New Deal era of the 1930s, the firm became one of the leading recipients of Public Works Administration bridge projects, including the Harlem River Triborough Bridge and the South Omaha Bridge over the Missouri River.

During the 1930s, Ash-Howard-Needles & Tammen was one of the most active designers of movable spans in New Jersey. In 1930 the firm completed work on the Burlington-Bristol vertical lift bridge across the Delaware River from New Jersey to Pennsylvania. Their work also included the bascule bridges for the Ocean Highway in Cape May County (Bridge No's 3900003-6) and over 6 bascule bridges for the New Jersey State Highway Department. The Oceanic Bridge is one of the best maintained and least altered of the group. In the 1940s the firm continued its activities in the state as the general consultant for the New Jersey Turnpike, and as the designers of the Delaware Memorial Bridge. Ash-Howard-Needles & Tammen played a significant role in the development of New Jersey's highway system.

The Oceanic Bridge appears to have no significant major repairs or alterations. In 1954 the primary power cables was replaced. In 1965 repairs were made to the concrete piers and piles. In 1970 the deck was repaired. In 1983 the northern curved seawall approach was reconstructed. In 1984 the operator's house windows were replaced. In 1992 the approach span piers were reconstructed.

Boundary Description and Justification: The bridge is individually distinguished, in and of itself, and the boundary is thus limited to the superstructure, substructure, and right-of-way over the river.

SETTING / CONTEXT The two-lane bridge with sidewalks spans the mill pond spillway in the Imlaystown Historic District, an 18th- and 19th-century village of about 2 dozen residences and mill building. The village's main section is north of the bridge but a number of buildings are also found on the south side of the creek. The mill pond has fallen out of repair and has grown over with weeds.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Imlaystown Historic District. 01/03/1985. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1925 single span encased steel stringer bridge with concrete abutments, pipe railings, and timber spillway gate frame is a representative example of a common early-20th century bridge type. It is not within the period of significance of the Imlaystown Historic District (c.1700-1900), and does not contribute. Portions of the structurally associated dam, mill raceway system, and pond may be considered contributing to the district's historic character, but not the bridge based on its date.

DESIGNER/PATENT GEORGE D. COOPER, CO. ENG. **BUILDER** THOMPSON & MATTHEWS CO.

SETTING / CONTEXT The 2-lane bridge with sidewalks spans the concrete mill pond spillway in the Allentown Historic District, a large district incorporating the 18th, 19th, and early-20th century houses and commercial buildings in downtown Allentown. Next to the bridge is the old mill now converted to a gallery and restaurant. On either side of the crossing are numerous well-preserved historic houses in mature neighborhoods.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Allentown Historic District. 04/27/1982. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1921 single-span steel deck girder with floorbeams bridge has concrete abutments with wing walls, pipe railings, and an 8-bay concrete spillway gate frame between its upstream wing walls. The bridge was built within the period of significance of the Allentown Historic District (c.1700-1941), and is thus evaluated as contributing structure. It is a part of the historic water power system and is a representative example of period bridge technology. It is not individually noteworthy.

INFOR MATION

Bibliography:
Monmouth County Engineer. Bridge Plans for Bridge Number U-12. 1921.
Office of New Jersey Heritage. Monmouth County: Allentown Historic District Nomination. 1982.

Physical Description: The bridge is a single-span, built-up deck girder with concrete-encased floor beams. The girders rests on concrete abutments with older masonry back and wingwalls. The bridge spans the spillway from an old mill pond, and built into the upstream side of the bridge is an eight-bay concrete spillway gate frame with wood gates. The bridge has two cantilevered sidewalks with pipe railings. Beam guide rails and chain link pedestrian fences have been added to the railings.

Historical and Technological Significance: The well-preserved 1921 deck girder bridge is within the boundaries of the Allentown Historic District, and is a contributing structure because it is was built within the district's 1780 to 1942 period of significance, and it illustrates the historic theme of community development (criterion A). The district is made up of numerous residential and commercial structures including the mill building, mill pond with raceway and metal water wheel west and south of the bridge. The bridge is not rated in the National Register nomination, although the bridge right-of-way is within the district boundaries and all of the adjacent buildings and lots are rated. The Main Street bridge is a representative example of early-20th century bridge technology, and it is historically associated with the impact of the automobile and highways on small rural villages such as Allentown. It is clearly related to the dates and broad historic themes associated with the district.

The bridge is located at a historic crossing, and in 1921 portions of the masonry abutments and wingwalls of a previous bridge were retained for the current deck girder's construction. What type of bridge was replaced is not currently known. The deck girder bridge with original pipe railings was designed by county engineer George D. Cooper and built by the Thompson and Matthews Company of Red Bank. A search of the county engineer's records revealed no major alterations to the deck girder bridge except for regular maintenance and repairs.

Boundary Description and Justification: The bridge is located in the National Register Allentown Historic District. The boundaries are delineated in the map that accompanies the nomination in the National Register files at the DEP Historic Preservation Office. The bridge is located within the specified boundaries, so the bridge is clearly within the district. Thus the bridge and its setting have been evaluated as significant.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The ca. 1915 rivet-connected Warren pony truss bridge with verticals, lattice railings, outriggers, and concrete abutments has been subjected to limited modifications. Like other truss bridges in Monmouth County, the floorbeams were all underpinned ca. 1945. There appear to have been no modifications to the trusses. Although timber stringers, not the trusses, support the live load, the loss of function of the trusses has minimal impact on the integrity of the structure. The 1915 date of construction is based on stylistic analysis of the bridge; no early records were located at the County Engineer's office. The bridge is one of four remaining in the County of this once common type. It is individually eligible for listing in the National Register of Historic Places under Criterion C as a representative example of a riveted Warren pony truss.

INFOR MATION

Bibliography:
Monmouth County Engineer. Inspection Report for Bridge U-23. 1949.

Physical Description: The bridge is a 3-panel rivet-connected Warren with verticals pony truss. It measures 40'-long and 15'-wide, and it is composed of standard rolled steel members. The upper chords, lower chords, diagonals, and verticals are all composed of riveted back-to-back steel angles. The flooring system consists of I-beam floor beams and new timber stringers with wood plank deck with asphalt wearing surface. The floor beams have been underpinned with timber piles, so the span now functions with live loads as a stringer rather than a truss span. The abutments are concrete. The bridge has lattice railings and rivet-connected outriggers that appear to be original.

Historical and Technological Significance: The Harvey Road Warren truss bridge is one of four similar examples of the type in the county (130MT21, Locust Avenue over Claypit Creek, c.1910, Middletown Twp.; 1300A23, Creamery Road over Yellow Brook, c.1910, Colts Neck Twp.; 1300U26, Smith Mill Road over Lahaway Creek, c.1915, Upper Freehold Twp.), but modifications to the way in which live loads are supported have significantly altered its technological and historical value. A review of the old plans and photographs located in the county engineer's office revealed that Warren pony truss bridges were common in Monmouth County. However, this example has no significant construction details, is only 40' long, and does not have integrity of original design. Additionally, it is undocumented. No records of the builder, date of construction, or plans survive with the county engineer. A 1949 inspection report indicates that the truss had been underpinned by that date. The county engineer underpinned most of the truss bridges in the 1940s and 1950s, and all of the known surviving highway truss bridges in the county have been underpinned. The Harvey Road bridge stylistically dates from ca. 1915, and is a representative but undistinguished example of pony truss bridge technology. Its rural setting is appropriate to its original historic context.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-panel rivet-connected Warren pony truss with concrete-capped masonry abutments was underpinned at each floor beam ca. 1950. Timber stringers bearing on the original floor beams have been added, and the bridge now functions as a 3-span stringer rather than a truss bridge. No bridge plans survive at the county engineer's office. An altered example of a well represented bridge type in the area, the undocumented span has no distinguishing details nor historical associations.

INFOR MATION

Bibliography:
Monmouth County Engineer. Bridge Inspection Report for Bridge Number U-26. 1948.

Physical Description: The bridge is a 3-panel rivet-connected Warren pony truss. It measures 42'-long and 15.9'-wide, and is composed of standard rolled steel members. The upper chords, lower chords, and diagonals are all composed of riveted steel angles with gusset plates. The flooring system consists of I-beam floor beams, steel stringers reinforced with timber stringers, and a wood plank deck with an asphalt wearing surface. The bridge has outriggers with welded connections at the top chords and floor beams. They appear to be original elements that have been reconnected. The abutments are masonry with concrete repairs. The bridge has been underpinned with three timber pile bents supporting each floor beam. New 4x12 timber stringers have been added. They are deeper than the steel stringers, so the new timber stringers bearing on the floor beams and the abutments are what carry the live loads. The original railings have been removed and replaced with beam guide rails.

Historical and Technological Significance: The ca. 1915 Smith Mill Road Warren pony truss bridge is a standard design of its type with no distinguishing construction details, and it has been altered. While the trusses themselves appear to be complete, the placement of piles to support the floor beams (underpinning) and the addition of timber stringers to carry the deck and live load have functionally changed the span from a truss bridge to a stringer. The original design of the undistinguished bridge has been altered.

The county engineer's files offered no records of the Smith Mill Road bridge builder or date of construction nor any plans. The lack of documentation further detracts from its historic value. The bridge's style of construction suggests that it dates from ca. 1915. A 1948 inspection report lists the bridge in "poor condition." It is probable that shortly thereafter the truss was underpinned, a common practice in Monmouth County. In the last forty years the bridge's setting has changed from rural to suburban residential.

The bridge is one of four Warren trusses in the county (130MT21, Locust Ave. over Claypit Creek, c.1910, Middletown Twp.; 1300A23, Creamery Road over Yellow Brook, c. 1910, Colts Neck Twp.; 1300U23, Harvey Road over Miry Run, Upper Freehold Twp.). A review of old plans and photographs located in the county engineer's office revealed that Warren pony truss bridges were common in Monmouth County. The multi-span Locust Ave. bridge (130MT21) is the most technologically distinguished of the surviving bridges of this type and design.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY In 1943 the bridge was built as a two-span laminated timber slab with timber pile bents and timber sheet pile back walls. In 1961 the bridge was rebuilt with a prestressed-concrete box beam superstructure on timber pile bents. The bridge is not historically or technologically distinguished based on its type and age.

SETTING / CONTEXT The two-lane bridge spans the concrete spillway of a mill pond dam. The spillway gates have been removed, and the mill no longer exists. The mill foundations are in the undergrowth to the northeast of the bridge. The neighborhood is now lightly-developed residential with a mixture of new and old homes.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span deck girder bridge consists of two 20" rolled I-beam girders with six 10" floorbeams with concrete jack arches. The northern abutment is masonry and the southern abutment is concrete. Original construction records were not located at the county engineer's office, but stylistically it appears to date ca.1920 on an older masonry substructure. In 1959 the bridge was widened on one side with prestressed box beams. It is not historically or technologically distinguished.

SETTING / CONTEXT The single-lane bridge spans Crosswicks Creek in Walnford County Park, a National Register Historic District with grist mill (1871) and house (1773) to the northeast of the bridge. The picturesque historic site was the home of a prominent Quaker family. Just north of the bridge on Walnford Mill Road is a steel stringer bridge with Phoenix Column piers spanning the flood plain of Crosswicks Creek (1300U47).

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Walnford Historic District. 06/29/1976. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The pin-connected 4-panel Pratt pony truss has Phoenix Column top chords and end posts. In 1885 the Phoenix Bridge Company fabricated the truss for erection by New York City engineers Dean & Westbrook. In 1948 the bridge was underpinned with timber piles. The masonry abutments have been repaired with concrete numerous times. The bridge no longer functions as a truss, but its technological significance and date make it a contributing element to the Walnford Historic District (c.1770-1900).

INFOR MATION

Bibliography:
Burnham, Alan. "Forgotten Engineering: The Rise and Fall of the Phoenix Column." Architectural Record. April 1959.
Harshbarger, Patrick and Mary McCahon. A. G. Lichtenstein & Assoc. "New Jersey Phoenix Column Bridges." Paper for Society for Industrial Archeology. Pittsburgh, June 1993.

Office of New Jersey Heritage. National Register File: Monmouth County; Walnford Mill Historic District, 1976.
Phoenix Bridge Company Records. History of Orders, 1885. Accession 916. Hagley Museum and Library. Wilmington, Delaware.

Physical Description: The bridge is a 4-panel, cast and wrought-iron pin-connected Pratt pony truss with Phoenix Column sections for the upper chords and inclined end posts. The two members are joined by cast pieces. The lower chords are stamped eye bars, the verticals are angles with lacing, and the diagonals are loop welded eye bars. The counters are connected to the upper panel point by a clevis rather than an eye. The bottom connection, however, is the traditional eye loop. Another unusual feature is the outriggers which are similar to those on a 1885 Dean and Westbrook Phoenix column pony truss bridge in Hunterdon County (10XXF65, Hamden Road over South Branch of the Raritan River, Franklin Twp.). The outriggers on this bridge have been reconnected by welds, so while an original detail, the way they are connected is not. The trusses bear on girders that rest on masonry abutments that have numerous concrete repairs and reinforcing. The placement of the built-up floor beams above the lower chord with bolted connections is an original detail.

Braced timber pile bents with I-beam cap beams have been placed at each floor beam to underpin the trusses. Deep timber stringers bear on the bents, so the span now generally functions as a timber stringer bridge rather than a truss span. Other alterations include removal of the original railings and installation of beam guide rails. There are some minor repairs and strengthening.

Historical and Technological Significance: The Pratt pony truss bridge is a historically noteworthy example of late-19th century iron truss bridge construction using the patented Phoenix Column section. Walnford Road is the western border of the Walnford Mill Historic District, an eighteenth and nineteenth century historic site with large dwelling house (c.1773) and grist mill (c.1871) administered by the Monmouth County Park Commission. The bridge is a contributing structure and is eligible under both Criteria A and C of the National Register for its association with the historic events surrounding Walnford Mills, and as an example of a rare surviving bridge type embodying the characteristics of a significant type, period, and method of bridge construction. It was constructed within the period of significance of the historic district, and it retains its historic appearance.

Phoenix Bridge Company records date the Walnford Mill Road bridge to 1885. The company fabricated the bridge in its shops at Phoenixville, Pennsylvania under order from New York City engineers Dean and Westbrook. From the mid-1880s to the early 1890s Dean and Westbrook held an agreement with the Phoenix Bridge Company as agents for the construction of Phoenix Column highway bridges. Dean and Westbrook took responsibility for bidding the bridges, signing contracts with local officials, providing accurate information for Phoenix engineers to prepare plans and shop orders, and erecting the bridges on site. In New Jersey from 1885 to 1895 Dean and Westbrook erected at least 71 documented Phoenix Bridge Company truss bridges, of which six are known to survive (10XXF65, Hamden Road over South Branch of Raritan River, 1885, Franklin Twp., Hunterdon Co.; 10XXF82, Lower Lansdowne Road over Capoolong Creek, 1885, Franklin Twp., Hunterdon Co.; 1300U53, Province Line Road over Crosswicks Creek, 1891, Upper Freehold Twp., Monmouth Co.; 020042A, Doty Road over Ramapo River, 1891, Oakland Borough, Bergen Co.; 020044B, Elm Street over Hackensack River, 1892, Oradell Borough, Bergen Co.).

The patented Phoenix Column was developed in 1864 by David Reeve of the Phoenix Iron Company of Phoenixville, Pennsylvania. Its significance in the history of civil engineering was as a leading contribution to the substitution of wrought iron for cast iron in the compression members of bridges and buildings. It enjoyed tremendous popularity in the 1880s, and was important in the general acceptance of metal truss bridge technology. In the late-19th century the Phoenix Bridge Company, an offshoot of the Phoenix Iron Works, was one of the nation's leading innovators in structural iron and steel construction and a training ground for numerous civil engineers.

Although the Walnford Road bridge has been altered and no longer functions as a truss, it retains enough integrity of design to be

A. G. Lichtenstein & Associates, Inc. performed initial survery.

Correction Updates Etc should be sent to
Correspondence.Unit@DOT.State.NJ.US
November 12, 2002

considered an important example of a rare bridge type. Its significance is greatly enhanced by documentation of its construction in the Phoenix Bridge Company records. Company order books include casting and forging instructions for every bridge member, and it is possible to follow the truss fabrication from iron foundry and roll mill to machine shop. This level of documentation is rarely encountered and in combination with records that survive for other Phoenix Column trusses provides a laboratory for the study of late 19th-century bridge construction technology.

The Walnford Road bridge spans Crosswicks Creek at the Walnford Mill Historic Site. The Walnford Mill Historic District nomination lists the Walnford Road as one of the western boundaries of the district. The bridge was not rated in the nomination, but it appears to be within the district. It was built within the period of significance (c.1700-1899) of the district, and it contributes to the themes developed in the nomination. It is therefore a contributing resource.

The bridge played an important role in the transportation system that linked the mill, active until about 1929, with the surrounding country side, and it helped make the mill the economic center of the local agricultural-based economy. The historic crossing has been in use since at least the eighteenth century, and the current truss is the last of several bridges that have stood at or near the present right-of-way. The truss is an important element of the district's historic character. It is located just downstream from the grist mill, and is south of a stringer bridge with Phoenix Column piers that spans the river flood plain (1300U48).

Inspection reports and alteration plans at the Monmouth County Engineer's office indicate that in 1948 the bridge was underpinned. The timber pile cap beams were welded to the truss floor beams, new bridge seats poured, and the existing stone and concrete abutments repaired. Timber bulkheads were added. In 1969 the timber stringers and deck were reconstructed.

Boundary Description and Justification: The Walnford Road bridge is a contributing structure to the Walnford Mill Historic District. Walnford Road forms the western boundary of the district, but revisions to the nomination are currently underway to amend it to specifically rate the bridges and include newly acquired property on the east side of Walnford Road. Because the bridge is part of a larger historic setting, both it and its surroundings are evaluated as significant.

CONSULT STATUS Individually Eligible. Listed. Walnford Historic District. 06/29/1976 Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY In 1893, according to Phoenix Bridge Company records, the bridge was built as a 4-span rolled I-beam stringer supported on Phoenix Column bents. In 1943 timber pile bents and timber stringers were added to what is now an 8-span bridge. Original pipe railings were removed and beam guide rails added. The bridge is technologically significant because of the presence of the rare Phoenix Column bents, and it contributes to the historic district (c.1770-1900) based on date of construction.

INFOR MATION

Bibliography:
Burnham, Alan. "Forgotten Engineering: The Rise and Fall of the Phoenix Column." Architectural Record. April 1959.
Hunton, Gail, Monmouth County Parks Historian. Phone Conversation with J. Patrick Harshbarger, December 4, 1992.
Monmouth County Engineer. Bridge File: U-48.
Office of New Jersey Heritage. National Register Files: Monmouth County; Walnford Mill Historic District Nomination. 1976.
Phoenix Bridge Company Records. History of Orders, 1893. Accession 916. Hagley Museum and Library. Wilmington, Delaware.

Physical Description: The bridge is a metal and timber stringer span supported on brick abutments and bents. The bent columns are wrought-iron Phoenix Column sections, and the cap beams are built-up floor beams. The rolled I-beam stringers and Phoenix Column piers are rusted and deteriorated in spots. Newer timber stringers have been alternated with the metal stringers, and timber pile bents has been added, changing the bridge from a four span to an eight span configuration. The single-lane bridge has a plank deck with an asphalt wearing surface and beam guide rails.

Historical and Technological Significance: The bridge is a historically and technologically significant example of the use of Phoenix Column bents for a bridge's substructure. It is the only example of its type in the state. Walnford Mill Road is the western border of the Walnford Mill Historic District, an eighteenth and nineteenth century historic site with large dwelling house (c.1773) and a grist mill (c.1871) administered by the Monmouth County Parks Commission. The bridge is a contributing structure and is eligible under both Criteria A and C of the National Register for its association with the historic events surrounding Walnford Mills, and as an example of a rare surviving bridge type embodying the characteristics of a significant type, period, and method of bridge construction. It was constructed within the period of significance of the historic district, and retains its historic appearance.

Phoenix Bridge Company records show that the bridge's date of construction is 1893. The Phoenix Column bents were fabricated at the company's Phoenixville, Pennsylvania shops under order from New York City engineers Dean and Westbrook and shipped to Monmouth County via the Pennsylvania Railroad. Dean and Westbrook acted as agents for Phoenix Bridge Company highway bridges and took responsibility for bidding bridges, signing agreements with local officials, and erecting bridges on site. Instructions for the Walnford Mill Road bridge specify an "iron and steel flood bridge" with five Phoenix Column bents, six lines of rolled I-beam stringers, and pipe railings. Walnford Road across Crosswicks Creek was reportedly realigned in the late-nineteenth century, and the flood bridge over the river's floodplain may have been part of the realignment.

The patented Phoenix Column was developed in 1864 by David Reeve of the Phoenix Iron Company of Phoenixville, Pennsylvania. Its significance in the history of civil engineering was as a leading contribution to the substitution of wrought iron for cast iron in the compression members of bridges and buildings. It enjoyed tremendous popularity in the 1880s, and was important in the general acceptance of metal truss bridge technology. The most noted example of its use in a substructure was for the piers of the New York City Second Avenue Metropolitan Elevated Railway (1878).

The Walnford Road bridge spans Crosswicks Creek at the Walnford Mill Historic Site. The Walnford Mill Historic District nomination lists the Walnford Road as one of the western boundaries of the district. The bridge was not rated in the nomination, but it appears to be within the district. It was built within the period of significance (c.1700-1899) of the district, and it contributes to the themes developed in the nomination. It is therefore a contributing resource.

The bridge played an important role in the transportation system that linked the mill, active until about 1929, with the surrounding country side, and it helped make the mill the economic center of the local agricultural-based economy. The historic crossing has been in use since at least the eighteenth century. It is located just downstream from the grist mill, and is north of a Phoenix Column pony truss that spans the river (1300U48). The pony truss dates to 1885 and was also constructed by Dean and Westbrook.

Inspection reports and alteration plans at the Monmouth County Engineer's office indicate that in 1943 modifications were made to the

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 7-panel, 110', pin-connected Pratt thru truss has Phoenix Column upper chords, vertical, and upper laterals, finials atop the portals, loop-forged eye-bar lower chords and diagonals, built-up floorbeams, and cast-iron connecting nodes. In 1943 the bridge was underpinned with steel stringers on timber piles. The span was constructed with patented Phoenix sections by well-known engineers Dean & Westbrook. It is a historically and technologically distinguished example of a rare type.

INFORMATION

Bibliography:
Burnham, Alan. "Forgotten Engineering: The Rise and Fall of the Phoenix Column." Architectural Record. April, 1959.
Darnell, Victor. Directory of American Bridge-Building Companies, 1840-1900. Washington, D.C.: Society for Industrial Archaeology, 1984.
Monmouth County Engineer. Bridge File: U-53.
Phoenix Bridge Company Records. Accession 916. Hagley Museum and Library. Wilmington, Delaware.

Physical Description: The bridge is a single-span seven-panel wrought and cast iron Pratt thru truss with patented Phoenix Column section for the upper chords, portals, upper lateral bracing, and verticals. The bottom chords consist of circular-headed eye bars. The principal diagonals and end panel hangers consist of needle-headed or loop forged eye bars. The center panel counters are rods. All panel points of the truss except the end panel hangers consist of cast iron pieces to receive the Phoenix Column sections. The built-up floor beams are supported by U-shaped hangers from the lower panel point pins. The floor beams support timber stringers with a plank deck and asphalt wear surface. The portals have decorative finials, and builders plaques that read "1891, Built By Dean & Westbrook, Bridge Engineers, New York." The abutments and wingwalls are rubble stone masonry.

The truss bridge has been altered by the addition of underpinning. Timber piles capped by a longitudinal beam stiffening member have been placed under each end of each floor beam. Additional timber floor beams supported on wood block risers and the longitudinal beams have been added at mid panel. The structure is in effect a six-span continuous deck girder bridge.

Historical and Technological Significance: The bridge is historically and technologically significant as an example of late-nineteenth-century iron truss bridge technology using patented Phoenix Column sections (criterion C). The pin-connected Pratt thru truss became the most successful and technologically important of the late-nineteenth century iron truss bridge types. Furthermore, the Province Line Road truss employs wrought iron Phoenix Columns. The patented Phoenix Column was developed in 1864 by David Reeve of the Phoenix Iron Company of Phoenixville, Pennsylvania. Its significance in the history of civil engineering was as a leading contribution to the substitution of wrought iron for cast iron in the compression members of bridges and buildings. It enjoyed tremendous popularity in the 1880s, and was important in the general acceptance of metal truss bridge technology.

The Province Line Road bridge was fabricated in 1891 by the Phoenix Bridge Company of Phoenixville, Pennsylvania and erected by Dean and Westbrook of New York City. Dean and Westbrook acted as agents for Phoenix Bridge Company highway truss bridges from the mid-1880s to the mid-1890s. Phoenix Bridge Company records show that Dean and Westbrook built over 70 Phoenix Column truss highway bridges in New Jersey from 1885 to 1895, and at least six including the Province Line Road bridge are extant (10XXF65, Hamden Road over South Branch of Raritan River, 1885, Franklin Twp., Hunterdon Co.; 10XXF82, Lower Lansdowne Road over Capoolong Creek, 1885, Franklin Twp., Hunterdon Co.; 1300U47, Walnford Mill Road over Crosswicks Creek, 1885, Upper Freehold Twp., Monmouth Co.; 020042A, Doty Road over Ramapo River, 1891, Oakland Borough, Bergen Co.; 020044B, Elm Street over Hackensack River, 1892, Oradell Borough, Bergen Co.). Of the six surviving trusses only two, the Province Line Road and Lower Lansdowne Road bridges are thru trusses, the others are pony trusses.

Because of the engineering significance of the Phoenix section, the bridge is evaluated as significant despite the fact that it was underpinned in 1943 and no longer functions as a truss bridge. The historic trusses appear to survive in basically unaltered condition.

Boundary Description and Justification: It is the trusses that are individually significant, not the later underpinning or altered substructure. The boundary is limited to the trusses themselves.

SETTING / CONTEXT The two-lane bridge with two sidewalks spans a bulkhead-lined tidal stream north of Glimmer Glass. The residential neighborhood consists of mid- to late-20th century houses, some seasonal and some converted to year-round. There are too many alterations to the cottages for the area to be evaluated as a potential historic district.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1930 two-span encased steel stringer bridge has concrete balustrades, paneled fascia, concrete abutments and pier, and pipe railings on the approaches. It is a standard county design and a common type. It is not historically or technologically distinguished.

DESIGNER/PATENT JOHN T. SIMPSON **BUILDER** OWEN MELEE

SETTING / CONTEXT The two lane bridge with two sidewalks spans Wreck Pond on the corporate line between Spring Lake to the north and Sea Girt to the south. The neighborhood is a well-maintained coastal resort community with late-19th and early 20th-century detached houses bordering the lake. Spring Lake Borough is a National Register multiple property listing (1870-1935) including hotels and boarding houses, residences, churches, commercial and civic buildings, and landscape and recreation structures.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Spring Lake Multiple Property. 03/08/1991. Contributing.

CONSULT DOCUMENTS SHPO Letter 3/12/01

SUMMARY The 1916 reinforced concrete arch has paneled parapets with posts with stepped caps. Within the boundaries of the Spring Lake multiple property listing, the unaltered bridge appears eligible under the nomination's specified criteria for landscape and recreation structures. It spans Wreck Pond, a naturally occurring recreational feature and park, and is part of the street plan and general landscaping and public improvements that contributed to Spring Lake's transformation into a resort community. The bridge is individually eligible for listing in the National Register under Criteria A and C, and is a contributing element of the Spring Lake Multiple Property District.

INFOR MATION

Bibliography:
Office of New Jersey Heritage. National Register File: Monmouth County; Spring Lake, New Jersey as a Coastal Resort, 1870-1935, 1990.

Physical Description: The First Avenue bridge carries two lanes of traffic with two sidewalks over Wreck Pond. The bridge is a 77-foot span reinforced-concrete elliptical arch. It has concrete parapets with paneled posts with stepped caps. The parapets extend over the long, plain concrete wing walls. Utility pipes have been added on the downstream side of the bridge. The span appears to survive in unaltered condition.

Historical and Technological Significance: The First Avenue reinforced concrete arch bridge built in 1916 is significant for its historical association (Criterion A) with the development of Spring Lake as a shore resort from 1870 to 1935. It meets the registration requirements for landscape and recreational structures (Property Type #5, Section F, pp. 23-28) in the 1990 Spring Lake Multiple Property Documentation Form. Spring Lake is a well-preserved resort community with numerous surviving hotels, summer residences, churches, civic and business buildings, and landscape features. It is representative of several Jersey Shore resorts that in the late nineteenth century were established and promoted by real estate developers.

The Spring Lake Multiple Property Documentation Form did not develop bridges as a specific property type, but it did broadly define general landscape and recreational structures as "the various interventions which contributed to Spring Lake's transformation from a farming to a resort community." It listed as examples of possible eligible types tree-lined streets, the grid street pattern, boardwalks, public parks, and lakes.

The First Avenue bridge, constructed in 1916, was part of the efforts that changed Spring Lake's natural landscape into a cultural landscape. The bridge spans Wreck Pond, a feature mentioned in the multiple property nomination as conspicuous for little premeditated landscaping, and as important for suggesting "the way the early resort must have looked like." The bridge was indicative of human intervention into the natural landscape, and was historically associated with efforts to improve streets and highways in the growing shore resort. The reinforced-concrete arch bridge type was considered as aesthetically appropriate for parks and naturalistic landscaping, and it was not surprising that it was chosen for this location. Bridge plaques indicate that the bridge was designed by engineer John T. Simpson under the supervision of county engineer George D. Cooper. Owen Melee constructed the bridge and was known to be active in the construction of several other early reinforced-concrete bridges in Monmouth County. The bridge is technologically representative of period reinforced concrete arch construction, and conveys the context of the multiple property nomination through its design, setting, materials, workmanship, feeling, and historical association.

No plans or records of bridge construction were located at the county engineer's office.

Boundary Description and Justification: The bridge is eligible under the existing registration requirements spelled out in the 1990 Spring Lake Multiple Property Documentation Form National Register nomination. The boundaries of the nomination are the Spring Lake Borough corporate boundaries. Wreck Pond is Spring Lake Borough's southern corporate boundary and the bridge spans the pond, so it is within the National Register listed area.

DESIGNER/PATENT ASH, HOWARD, NEEDLES & TAMMEN **BUILDER** MERRIT-CHAPMAN & MCLEAN

SETTING / CONTEXT The two-lane bridge with sidewalks spans the Shark River, which forms the border between Avon-by-the-Sea Borough and Belmar Borough, beach resort towns originally developed in the late-19th and early-20th centuries. Ocean Avenue parallels the beach. The bridge is located at the mouth of the navigable Shark River, and is one of the busiest movable spans in the state, opening an average of over 8,000 times per year.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The double-leaf bascule bridge with two encased haunched deck girder approach spans has concrete mechanical houses, cantilevered sidewalks with sheet metal balustrades, and concrete substructure. Originally designed in 1936 by Ash-Howard-Needles-Tammen, the bridge was extensively rebuilt in 1987 with new welded deck girder leafs, speed reducers, electrical wiring, and locks. The span is too altered to be significant. Distinguished examples of the bridge type remain in the county (1300S31).

INFOR MATION

Bibliography:
Monmouth County Engineer. Bridge File: W-43.

Physical Description: The main span of the 3-span haunched deck girder with floor beams bridge is a double-leaf trunnion bascule. The approach spans are encased. The substructure consists of concrete abutments and piers. The double-leaf bascule span is operated by means of pinions which engage racks attached to the main girders. The main girders have been rebuilt, the original riveted girders replaced with all new welded-stiffener plate girders. The pinions are operated through a train of gears connected to electric motors with back up gasoline engines. While the span operates in the original manner, most of the fabric related to the movable leafs is new. The electric motors, racks, rack pinions, rack pinion shafts, primary and secondary reducing gears, brakes and locks are modern replacements as are the welded movable leaf girders with concrete counterweights attached to the tail ends. They are finished with metal sidewalk railings that repeat the style of the concrete balustrades of the approach spans. Automatic traffic signals and barriers also have been added to the bridge. The concrete operator's house and control panel are original, but the electrical systems have been updated with automatic controls for opening and closing.

The two-story concrete operator's houses on opposite sides of the double leaf bascule have rectangular floor plans and are Moderne in style with vertical scoring and lantern-style roof lines. The interiors have been remodeled. The roofs of the two one-story machinery houses provide observation platforms for pedestrians.

Historical and Technological Significance: The 1936 Ocean Avenue double-leaf bascule bridge is one of over a dozen regional examples of Ash-Howard-Needles & Tammen (AHNT) designed trunnion bascule bridges dating from the late 1920s-1930s. This one was built by the Merritt-Chapman-McLean Corporation. The bridge is not an early example of the bridge type, and it is highly altered. The movable leafs are welded girders placed in 1987, and the motors, racks, pinions, shafts, enclosed gears, brakes, and toe locks are also modern replacements. The approach spans enjoy more integrity than the movable span. Because of the loss of so much original fabric, this example of what is a well represented bridge type, is not historically nor technologically distinguished. More complete examples remain, and they better reflect the technological significance of the bridge type (see 1300S31, Oceanic Bridge over the Navesink River, 1939, Middletown Township). The patent associated with the AHNT design is for the trunnion tower. The design eclipsed the Strauss-designed bascule in popularity in the state in the late 1920s.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The western span of the 2-span bridge is a 1940 encased steel stringer with concrete balustrades, and its eastern span is a 1964 prestressed box beam with solid concrete parapets molded to appear like balustrades. In 1940, when the single encased steel stringer span was built, the NJ State Hwy. Dept. planned to eventually widen US 9 (former NJ 4). In 1964 the box beam span was added with matching Moderne detailing and parapets. The bridge is not historically or technologically distinguished.

SETTING / CONTEXT The two lane bridge with two sidewalks spans the Millstone River in a lightly-developed area of early-20th century houses and farmers' fields. The bridge is on a short stretch of old NJ 33 that in 1971 was bypassed immediately south by a four-lane divided highway. Across the divided highway from the bridge is a bank (c.1980).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed single-span deck girder with floorbeams bridge has concrete balustrades with stylized end consoles and a concrete substructure. Beam guide rails have been added. In 1926 the bridge was built as part of NJ Route 7 improvements. The highway was later redesignated NJ 33. In 1971 the old 2-lane highway was bypassed by a modern 4-lane divided highway. The bridge is a representative example of a common bridge type and is not historically or technologically distinguished.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 94' long, 5-panel pin-connected Pratt thru truss is one of two surviving metal thru truss highway bridges in the county. The superstructure appears complete with original basket-end hangers, railings, and plaques. In 1949 it was underpinned with timber pile bents at the beams and bearings. The span was fabricated by a nationally significant bridge manufacturer, the Wrought Iron Bridge Co. It is a well-preserved and technologically significant example of an increasingly rare bridge type.

Wrought Iron Bridge Company. "Illustrated Pamphlet of Wrought Iron Bridges Built By Wrought Iron Bridge Company, Canton, Ohio," 1885.

Physical Description: The 94'-long 5-panel pin-connected Pratt half hip thru truss bridge is composed of rolled sections. The top chords and inclined end posts consist of a built-up box member, and the lower chords are paired eye bars with loop-forged eyes. The verticals are toe-out channels with lacing, except for the hip verticals which are bar stock with basket-like ends to pick up the lower panel point pin. The diagonals are paired eye bars, and the counters single bars with turnbuckles. The I-beam floor beams are connected to the panel point pins by U-shaped hangers. The upper struts are channels with rivet-connected upper and lower plates, and the upper laterals are rods with turnbuckles. The A-frame portal bracing, which is composed of angles, carries a makers plaque. The stringers support an asphalt pan deck. The end bearings, which have been encased in concrete, rest on cylindrical riveted metal caisson-like columns with timber sheet pile back walls. The truss lines have metal lattice railings. It is not known whether the bridge is composed of steel and/or iron members, but given the 1899 date of construction, it is most likely steel.

The truss has been altered by the addition of timber pile bent with I-beam cap underpinning. The timber pile bents support I-beam girders which in turn support the original truss floor beams and a series of additional intermediate I-beam floor beams. The bridge structurally acts as a six-span deck girder.

Historical and Technological Significance: The 1899 Preventorium Road Pratt half hip thru truss bridge is historically and technologically significant as a reasonably well preserved example of an important late-19th century truss bridge type (criterion C). During the late-19th century, the Pratt truss type was one of the most common truss bridges in the country, and it played a role in the widespread acceptance of metal truss bridge technology. Pratt trusses were once very common in New Jersey, but only a small number survive. In Monmouth County only one other thru truss highway bridge is known to survive (1300U53, Province Line Road over Crosswicks Creek, 1891, Upper Freehold Twp.). While the bridge has been underpinned and does not function as a single-span thru truss span, the trusses have survived in basically unaltered condition which contributes to its historical and technological significance as does the fact that the bridge is documented.

The bridge was designed and fabricated by the Wrought Iron Bridge Company of Canton, Ohio. Organized in 1864 by David Hammond, the company was one of the first wrought iron truss manufacturers, and continued in existence for 36 years before being absorbed by the giant American Bridge Company in 1900. The company claimed in its promotional literature to have constructed trusses in 30 states, mostly east of the Mississippi River. In Canton, the fabricator had shops for the drafting, laying out, shearing, drilling, punching, and riveting of truss members, but did not roll its own iron or steel. The Wrought Iron Bridge Company was recognized as one of the most significant national manufacturers of iron and steel trusses because of its workmanship and prolificacy. Unlike many of its competitors, the Wrought Iron Bridge Company did not specialize in one truss type, but constructed a wide diversity of small and large, inexpensive and expensive truss types, depending upon local preferences. According to its 1885 catalogue, at least 10 Wrought Iron Bridge Company trusses were built in New Jersey prior to 1885, 6 in Middlesex County, 3 in Mercer County, and 1 in Union County. Two other Wrought Iron Bridge Co. bridges are known to survive in Somerset County, the well-preserved Nevius Street Bridge (1886, 18E0801, Raritan Borough), a two-span double-intersecting Pratt thru truss across the Raritan River in the town of Raritan, and the Higginsville Road over the South Branch of the Raritan River bridge (1893, 18A0605, Branchburg Twp.), a one-span Pratt thru truss similar to the Preventorium Road bridge in Monmouth County.

The Preventorium Road bridge is located on a dead-end road that provides access to the Howell Township Golf Course and County Park.

The golf course and park were once the grounds of the Farmingdale Preventorium. In 1909 the Preventorium was founded by a doctor from New York City as a radical measure to prevent children from contracting tuberculosis. Children, many poor and from immigrant families, were transported from the city to isolate them from crowded urban conditions and the threat of the disease. A number of the Preventorium buildings survive, and some have been converted to Township office buildings. The buildings are located on the opposite side of the golf course from the bridge. The Preventorium postdated the bridge by at least ten years, and was not associated with the bridge's construction, although it did eventually lend its name to the road.

County engineer's inspection records and plans indicate that in 1949 the truss was underpinned. Underpinning was a common practice in Monmouth County, and all of the county's surviving truss bridges have been similarly altered.

In summary, the Wrought Iron Bridge Co. was one of the most successful of the many small designers/fabricators who dominated 19th-century bridge construction. The Preventorium Road bridge is an important example of their craftsmanship, as well as a significant example of a bridge type that was once common in Monmouth County and New Jersey as a whole.

Boundary Description and Justification: The bridge is individually eligible, and it is the trusses and original substructure, not the later underpinning or alterations that are significant. The boundary is limited to the original portions of the bridge and the substructure.

SETTING / CONTEXT The two-lane bridge with wood plank sidewalk spans Claypit Creek, a tidal tributary of the Navesink River. It is located within the boundaries of Navesink Village Historic District, an 18th- and 19th-century maritime and commercial community with workers' housing, general stores, mill sites, and churches on both sides of Claypit Creek. The district survives within a suburban area that is heavily developed with late-20th century housing.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Navesink Village Historic District. 08/08/1975. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The originally 5-span, 5-panel riveted Warren truss bridge is the only multi-span example of its type in the county. The trusses are well preserved, although like all other trusses in the county, it has been underpinned with timber pile bents. No early records were with the county engineer, but the bridge's style dates c.1910, placing it outside the dates of significance of the historic district. It is a technologically significant example of an increasingly rare truss type.

INFORMATION

Bibliography:
Monmouth County Engineer. Bridge File: MT-21.
Office of New Jersey Heritage. National Register File: Monmouth Co.: Navesink Historic District Nomination. 1975.

Physical Description: The 408-foot long bridge spans tidal Claypit Creek near its confluence with the Navesink River in Middletown Township. The bridge consists of five rivet-connected Warren pony truss spans made of standard rolled steel members. The upper and lower chords are toe-in angles with web plates, and the diagonals are angles set back-to-back. The floor system consists of built-up floor beams, timber stringers, and steel grid deck. The bridge has angle outriggers and pipe railings attached to the trusses. The five-panel trusses bear on riveted cylindrical steel piers with struts. The trusses have been underpinned with braced timber pile bents at each truss floorbeam creating a 24-span structure. The northern piers have an ashlar back wall and wingwalls. Beam guide rails and a utility pipe have been added.

Historical and Technological Significance: The ca. 1910 Locust Avenue bridge is technologically significant as an multi-span example of an increasingly rare metal truss bridge type that was once common in Monmouth County. It is one of four similar Warren pony truss bridges in the county; all have been underpinned, which compromises their integrity of design, and none are documented as to date of construction or fabricator (1300A23, Creamery Road over Yellow Brook, Colts Neck Township; 1300U23, Harvey Road over Miry Run, Upper Freehold Township; 1300U26, Smith Mill Road over Lahaway Creek, Upper Freehold Township). This example has been evaluated as locally significant because it is the only multi-span example in county and because it has the cylindrical riveted columns supporting the bearings. They are not a common construction detail. The trusses themselves have no significant construction details, but are representative examples of what was one of the most popular highway bridge types during the first two decades the twentieth century. The riveted Warren pony truss played a significant role in the early-20th century county road improvement campaigns.

The county engineer's office has no records of the Locust Avenue bridge's builder or date of construction. Stylistically the bridge dates from ca. 1910. An inspection report indicates that in 1952 the truss was underpinned. The county engineer underpinned most of the county's truss bridges in the 1940s and 1950s, and all of the known surviving highway truss bridges in the county have been underpinned. In 1956 the steel grid deck replaced a timber deck.

The bridge is located within the stated boundaries of the Navesink Historic District, an eighteenth- and nineteenth-century maritime and commercial community with workers' housing, general stores, mill sites, and churches on both sides of the river. The early twentieth-century bridge does not contribute to the district's period of significance or historic themes. The community, however, retains much of the same character it had at the time of the bridge's construction.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including superstructure, substructure, and right-of-way over the river. Even though it is located within the National Register listed Navesink Historic District, the period of significance specified in the nomination is limited to the 18th and 19th centuries. The bridge should thus be evaluated as a noncontributing resource to the district based on its dates of construction.

NEW JERSEY HISTORIC BRIDGE DATA

STRUCTURE # 130MT50 **CO** MONMOUTH **OWNER** COUNTY **MILEPOINT** 0.0

NAME & FEATURE INTERSECTED MOUNT AVENUE OVER GRANDE AVENUE **FACILITY** MOUNT AVENUE

TOWNSHIP ATLANTIC HIGHLAND BOROUGH

TYPE STEEL ARCH **DESIGN** ELLIPTICAL **MATERIAL** Steel

 # SPANS 1 **LENGTH** 61 ft **WIDTH** 20.8 ft

CONSTRUCTION DT 1896 **ALTERATION DT** 1993 **SOURCE** INSCRIPTION

DESIGNER/PATENT JAMES MUSER **BUILDER** N. WOODWARD

SETTING / CONTEXT The bridge carries a two-lane street over a two-lane street with two sidewalks. It is located on Mount Mitchell, a peak overlooking Raritan Bay. The setting is residential with a mixture of late-19th to late-20th century suburban residences with numerous modern intrusions. The streets and house lots on Mount Mitchell were first laid out in the 1880s by the Hillside Park Improvement Company for the purposes of a summer resort and religious camp meeting association.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed, Melan-type steel-concrete arch bridge with highly decorative detailing ranks as one of the earliest examples of its type in the nation. The designer is not documented, but it is the earliest use of the technology in New Jersey. Built with curved steel open-web beams set in concrete, the span represents the transition to use of concrete in bridges. Its handsome rustic detailing is historically associated with the development of the Atlantic Highlands summer resort.

INFOR MATION

Bibliography:

Leonard, Thomas H. From Indian Trail to Electric Rail. Atlantic Highlands: Atlantic Highlands Journal, 1923.

Physical Description: The skewed 61'-long single-span elliptical arch bridge is an early example of a steel-concrete span composed of eight rolled I-beams encased in plain concrete. It is built on a skew of 53 degrees. The custom, rustic-style bridge is distinctively finished with rubble stone spandrels walls and parapets with caps of stones set on end. The stone parapets have built-in benches for pedestrians, and a curved stairway is located at the bridge's northwest approach. The parapets have stone pylons that terminated in planters. The bridge has large earth-filled approaches with masonry retaining walls. Date stones on the bridge read "1896, N. Woodward Builder" and "Oonuehkoi." The bridge is structurally unaltered, but there is moisture penetration damage. The masonry has been repointed with historically inappropriate grapevine joints. Historic photographs reveal that the original mortar was held back from the surface plane.

Historical and Technological Significance: The 1895-1896 steel-concrete bridge ranks as one of the historically most significant examples of its type in the nation owing to its date of construction and state of preservation (criterion C). It may well rank as the oldest large example of a Melan Arch in the country. It is older than the 1897 Wyckoff Avenue bridge over Ho-Ho-Kus Brook (020033E, Wyckoff Twp., Bergen County) and the 1898 West Broadway bridge over Passaic River (1600017, Paterson City, Passaic County) that were designed and built by Thacher & Keepers of Detroit. The bridge type, a series of parallel iron or steel beams curved to the profile of the soffit and encased in plain concrete, was developed by Viennese engineer Josef Melan. He received an American patent for his design in 1894, but the German-born engineer Fritz von Emperge is credited with popularizing it in this country. Edwin Thacher and William Mueser were two of the leading designers and builders of Melan bridges during the late 19th and early 20th centuries. Edwin Thacher (1839-1920) moved to New York and went into business with Mueser in 1901, and their firm, styled Concrete Steel Engineering Company, was responsible for several important examples of the technology, like the 1911 7-span bridge at Wichita, Kansas, and the 1914-15 6-span Hudson River bridge at Glens Falls, New York.

Although no plans have been identified, physical evidence reveals that the Mount Avenue bridge is a Melan-type arch. Historian Carl Condit in his endnotes specifically attributes the bridge's design to William Muesser of the Melan Arch Construction Company of New York City (p. 341). He states that Muesser compensated for the torsional stresses associated with Mount Avenue bridge's skew by placing three sets of transverse tie rods between the arch ribs approximately 4' on center. How he came by that data, as well as the information naming Muesser, is not cited. Locally available materials, including the Minutes of the Atlantic Highlands Borough Council, The Atlantic Highlands Journal, and The New York Times, do not cite Muesser or name a designer in association with the bridge. In these sources credit for the bridge is given to local resident George Lawrie.

Little is known about Lawrie, who is also not listed in The New York Times. He moved to Atlantic Highlands after 1890, and he owned property on the east side of the bridge. Lawrie spearheaded the drive to have the bridge built as a civic amenity in an area dominated by large, gracious Queen Anne-style "cottages." At its September 3, 1895 meeting, the Borough Council voted to repair the Mount Avenue bridge. In response to the need to work on the bridge, George Lawrie volunteered at the council's November 2, 1895 meeting that if "the borough would give him $800. toward building a stone bridge over Grand Avenue on Mount Avenue, he would guarantee subscriptions of $1,200. and upwards additional toward the cost of building said bridge with the total cost projected by Lawrie to be about $2,000." It is apparent that Lawrie already possessed plans for the proposed span as bids for its construction were to be opened on November 11, and plans "were on file at the clerks office." It was reported at the December 3 council meeting that no bids for the "new rustic stone bridge" were received, but at the 5 December meeting, it was recorded that "a bid was received for building a bridge over Grand Avenue on Mount Avenue from contractor Nimrod Woodward." The amount of the bid was $800. On 10 December 1895 it was noted that the old bridge had been torn down, thus clearing the way for the new steel-concrete span. George Lawrie served as "supervisor" of construction

of the new bridge, and he also solicited contributions to pay the $3,569.50 it cost to build it.
Atlantic Highlands Borough is a late-nineteenth and twentieth century seashore resort community. It began in the early 1880s under the auspices of the Atlantic Highlands Association, which purchased 300 acres of land for a summer resort and religious camp meeting. It was incorporated as a borough in 1891. Mount Mitchell, on which the bridge is located, was a popular spot for its expansive view of the Raritan Bay, and was the location of some of the town's earliest resort homes. At the mountain's summit was a municipal park with a lookout tower known as Observatory Park. The steepness of the drive made travel to the top difficult, and Mount Avenue was known locally as "break-neck hill." A circular street plan with house lots was laid out on the mountain by the town's land developers, and led to the need for a bridge to carry Mount Avenue over Grand Avenue and on up the hill. In the 1880s the Atlantic Highlands Association paid for the construction of a chestnut timber "dry" bridge at the crossing.

On August 15, 1896, at a dedication ceremony, George Lawrie turned the bridge over to the Borough. He named the bridge "Oonuenkoi" commemorating an Indian tribe that once live in the vicinity of Atlantic Highlands, thus explaining the mysterious inscription on the bridge's date stone. The local paper dubbed the bridge "An Ornament to the Town and an Eighth Wonder," and further claimed that "the structure spoke for the work of the builders and would do so for centuries perhaps."

Today the residential district surrounding the bridge is a mixture of late-nineteenth, early-twentieth, and late-twentieth century housing, and lacks the cohesiveness necessary for a historic district. Nonetheless, the bridge is historically associated with the development of one of the Jersey Shore's earliest resort communities, and is one of the area's most significant examples of the type of public improvements undertaken by local residents and governments to make their towns more attractive and amenable to seasonal visitors.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including superstructure, substructure, wingwalls, and retaining walls. It is located in an area that was developed in the late-19th century with large Queen Anne-style dwellings, but there are so many mid- to late-20th century infill buildings that the area probably does not have historic district potential. Several of the late-19th century structures, however, may be individually eligible. The Lawrie house was reportedly lost to fire in the 1920s or 1930s.

SETTING / CONTEXT The two-lane bridge with shoulders and sidewalk spans Lahaway Creek near the intersection of CR 539 and CR 537. A number of produce stands and small commercial buildings line the county roads. The area is mixed-use residential and agricultural with 19th- and 20th-century houses.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span encased steel stringer bridge has concrete balustrades and abutments with stepped wingwalls on the downstream side. In 1939 the bridge was constructed as part of NJ Route 37. The state highway transferred it to the county. The span is a representative example of a common NJ State Highway Department bridge type, and is not historically or technologically distinguished.

DESIGNER/PATENT SCHERZER ROLLING LIFT BR. CO. **BUILDER**

SETTING / CONTEXT The movable span bridge carries four lanes of traffic and a single sidewalk over a navigable river. The setting is a heavily-developed beach resort town with mostly late-20th century condominiums, detached houses, marinas, and restaurants. South of the bridge is the early-20th century Belmar Municipal Building. Parallel to the bridge is the North Jersey Coast Line railroad's Scherzer rolling lift bascule bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 01/10/92

SUMMARY The bridge has a single-leaf deck girder trunnion bascule main span with fixed concrete counterweight and five encased deck girder with truss lateral bracing approach spans. The movable span has been rehabilitated with new reduction gearing, electric motors, brakes, locks, controls, and remodeled operators houses. Several examples of better preserved and more historically distinguished single-leaf trunnion bascule bridges exist. This span is too altered to be evaluated as noteworthy.

INFOR MATION

Bibliography:
New Jersey Department of Transportation. Bridge Plans and Reports for Bridge 1311150, 1927-1990.
New Jersey Transit. New Jersey Transit Historic Bridge Survey, 1991.

Physical Description: The 540-foot long bridge over the navigable Shark River consists of a single-leaf bascule main span and five multi deck girder approach spans, two to the south and three to the north. The single leaf bascule has an overall span of 60', and consists of two haunched deck girders with floor beams and steel grid deck. The bascule is of the simple trunnion type with a concrete counterweight affixed to the heel end of the leaf. The counterweight dips into the river at high water, and the condition has caused serious deterioration. It is operated by means of pinions which engage segmental racks on each girder. The pinions are operated by sets of drive shafts and gears connected to electric motors with back up gasoline engines. The electrical system, motors, primary and secondary reducers, motor brake, machinery brakes, and locks are all modern replacements. The racks, pinions, and trunnions are original. Automatic traffic signals and barriers have been added to the bridge. The concrete operator's and machinery houses have been significantly remodeled with new windows, doors, roofing, and floor plans. A second floor has been added to the eastern machinery house to protect new electrical cabinets from high water. The bascule has its original metal railings.

The approach spans are encased deck girders. Each span consists of three girders with lateral bracing. The approaches have concrete balustrades and substructure. Modern highway lighting and beam guide rails have been added.

Historical and Technological Significance: The Route 35 over Shark River bascule bridge is one of several known surviving 1920s and 1930s movable spans on the shore. It retains some of its original appearance, but significant alterations have been made to the operating and mechanical systems and the machinery houses, thus limiting its technological significance. In 1961 the steel grid deck replaced a timber deck; in 1973 underwater repairs were made to the concrete piers; and in 1989-1991 a major rehabilitation of the operating systems was undertaken. Several better preserved and historically distinguished examples of 1920s and 1930s single-leaf bascule bridge technology exist in New Jersey including Mantoloking Road over Barnegat Bay (1938, Ocean County, Bridge Number 1506006), and four Ocean Highway Bridges (c.1932-40, Cape May County, Bridge Numbers 310003-6). In Monmouth County two well preserved examples of the technologically similar double leaf bascule bridge are the Oceanic Bridge over the Navesink River (1937-39, Bridge 1300S31, Middletown Twp.), and the NJ 36 over the Shrewsbury River Bridge (1932, Bridge 1315150, Highlands Borough).

The bridge was designed by the Scherzer Rolling Lift Bridge Company of Chicago. The company was famous for its rolling lift bridges, but also engineered and designed other movable bridge types. The NJ Route 35 bridge, a simple trunnion bascule, is not a rolling lift bridge, and is not a technologically or historically significant example of the firm's work. Immediately adjacent the NJ Route 35 bridge is a Scherzer rolling lift bridge (1937) that carries the New Jersey Transit North Jersey Coast Line. The railroad bridge has been recommended eligible in the 1991 New Jersey Transit Railroad Bridge survey.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The four-lane bridge with Jersey barrier median and two sidewalks spans a small creek. NJ 35 is a suburban commercial strip, and adjacent to the bridge is a car dealership.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span encased steel stringer bridge with concrete balustrade and substructure has been widened on the upstream side with prestressed concrete box beams with concrete parapet. In 1927 the bridge was constructed as part of NJ Route 35, and in 1965 it was widened to accommodate a 4-lane divided highway. It is a common New Jersey State Highway Department bridge type, and is not historically or technologically distinguished.

DESIGNER/PATENT WADDELL & HARDESTY, NYC **BUILDER**

SETTING / CONTEXT The bridge carries four lanes of traffic and two sidewalks over the Shrewsbury River near its confluence with Sandy Hook Bay. The bridge connects the Highlands promontory on the mainland with the beach resorts on the peninsula. Twin Lights Historic Site (1862) overlooks the bridge. The setting is picturesque, but numerous modern intrusions such as restaurants, marinas, and a highway interchange at the entrance to Sandy Hook preclude a historic district adjacent the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 6/6/91

SUMMARY The main span of the 12-span bridge is a 140'-span double-leaf haunched deck girder trunnion bascule. The 11 approach spans are multi deck girders with concrete balustrades. The bascule retains its original or inkind replacement gearing, controls, and electrical systems. In 1931 the bridge was designed by the noted engineering firm of Waddell & Hardesty. It is an exceptionally well-preserved and beautifully situated example of early-20th century movable bridge technology.

The bridge is located between the beach resort towns of Avon-by-the-Sea and Belmar. The area is heavily developed with marinas, restaurants, stores, and late-19th to late-20th century seasonal and year-round homes and apartments.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 10-span haunched deck girder bridge has a double-leaf bascule with fixed concrete counterweights main span. The approach spans are encased. The bascule is one of over 12 in southeast New Jersey from the 1920s and 1930s designed by the noted firm of Ash Howard Needles & Tammen. A representative example of the type, the span is altered with new reducers, motors, controls, locks, electrical systems, and remodeled operators houses. The alterations make the span less significant than others.

INFOR MATION

Bibliography:
NJDOT. Plan File: 1321150.

Physical Description: The main span of the 860'-long 10-span bridge is a 90'-long double-leaf bascule. The two approach spans to the south and seven to the north are haunched deck multi girders on a concrete substructure. The bridge is finished with standard-design concrete balustrades, and the enclosures on the movable leafs are the same style executed in metal. Operators/machinery houses are set at each corner of the movable leafs. They have been remodeled with oversized metal pyramidal hip roofs and new metal windows and doors.

The movable leafs are composed of four haunched girders with floor beams and an open steel grid deck. The bascule leafs have fixed counterweights at the tail ends. Each leaf is operated by a pinion that engages a rack affixed to the outside of the fascia girders. While the trunnions and trunnion towers are original, the motors, controls, electrical systems, back up operation, primary reducers, motor brakes, machinery brakes, and locks are all new. The secondary reducers are original as are the racks and pinions. The operators' and equipment houses have also been redone.

Historical and Technological Significance: The 1932 NJ 71 bascule bridge over the Shark River is an altered example of the most common post-1925 movable bridge type in southeast New Jersey. It is one of over 12 patented Ash-Howard-Needles & Tammen movable bridges built between 1928 and 1941 in the Monmouth-Cape May County region. Many of the examples survive in unaltered condition. The Shark River bridge retains its integrity of function and some original or in kind replacement fabric. But, in comparison, this span is not a well preserved example and is thus less technologically significant than others of the same design built in the same time period. The patent related to the bridge addresses the design of the trunnion tower. More complete examples of bridges of the same design in Monmouth County are Oceanic Bridge over the Navesink River (1300S31, 1939, Middletown Twp.) and NJ 36 over the Navesink River (1315150, 1932, Highlands Borough).

TYPE THRU GIRDER **DESIGN** PARTIALLY ENCASED **MATERIAL** Steel

 # SPANS 1 **LENGTH** 69 ft **WIDTH** 19 ft

CONSTRUCTION DT 1917 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The two-lane bridge spans two tracks of New Jersey Transit's North Jersey Coast Line, the former New York & Long Branch RR, a division of the Central Railroad of New Jersey. The right-of-way was originally developed in the 1870s. The setting is residential with late-19th and early-20th century wealthy beach resort hotels and residences to the east, and late-20th century development to the west. The area near Deal Lake is a potential historic district or multiple property nomination.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Potentially eligible resort Historic District. May contribute.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span thru girder with encased floorbeams is one of the most architectonic of its type in the state. It has brick-faced abutments, terra cotta urns and scroll brackets, and brick detailing including planters and gateway. In 1917 the bridge was constructed as part of the development of the beach resort community, and is associated with other landscaping design elements such as brick walls and gates. It is a historically and aesthetically distinguished example of its type.

INFOR MATION

Bibliography:
History of Monmouth County, New Jersey, 1664-1920. New York: Lewis Historical Publishing Company, 1922.
Ocean Township. The Township of Ocean Commemorative Book. 1949.

Physical Description: The single-span riveted built-up steel plate thru girder with encased floor beams bridge is supported on brick-faced abutments. While the bridge itself has no distinguishing details, its decoration ranks among the most significant in the state. It is embellished with brick and terra cotta trim that matches that used for the walls and entrance gates that are adjacent to the bridge. Each corner of the bridge has a brick pedestal with large terra cotta consoles and topped by handsome oversized urn-shaped finals. Decorative brick panels have also been constructed between the concrete curbs and the top flange of the girders at every fourth panel across the bridge. The bridge is currently closed to vehicular traffic. The inside face of the girders is painted yellow. Some plate girder webs have rusted through in places. The span and its decorative elements survive unaltered.

Historical and Technological Significance: The 1917 Sydney Road overpass with its brick and terra-cotta detailing is one of the most architectonic thru girder bridges in the state. While the span itself is not technologically distinguished, the bridge is artistically noteworthy. It is historically associated with the social and economic development of the late-nineteenth and early-twentieth century seasonal resort residential community that borders Deal Lake. It is an integral part of the resort's cultural landscape and street plan. It is eligible under Criteria A and C of the National Register.

The bridge is located on the former grounds of the Hathaway House, a famous beachfront hotel that was popular during the late-nineteenth and early-twentieth centuries. In the 1910s the extensive hotel grounds, which stretched from the ocean to Deal Lake, were taken over for a residential development. The bridge was constructed as part of a larger landscaping plan for the residential development of the property. The brick-faced bridge abutments extend into terra-cotta tile topped brick walls that separate the residential areas from the railroad right-of-way. The eastern bridge approach at Sydney Road and Atlantic Avenue has a circular brick wall entryway with brick towers topped by urns. A sign in one of the towers reads "Deal Harbor." It is unknown whether Deal Harbor was the name of the development or the name of an estate house that may have stood on the western side of the bridge. No period house was identified on the west side of the bridge. Most of the houses date from after World War II.

Plans for the bridge were not located at NJDOT or at the county engineer's office. The railroad was developed in the 1870s by the New Jersey Southern Railway, a branch of the Central Railroad of New Jersey. The bridge is not of significance to the history of the railway, but is illustrative of the need to build above-grade crossings in response to increases in population and tourism at the Jersey shore during the early twentieth century.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including superstructure, substructure, wingwalls, boundary walls, and right-of-way over the railroad right-of-way. The surroundings do not have historic district potential.

DESIGNER/PATENT CENTRAL RAILROAD OF NEW JERSEY **BUILDER**

SETTING / CONTEXT The single-lane bridge spans a single abandoned track of the former Central Railroad of New Jersey's Freehold Branch. The right-of-way was developed in the late-1870s by the New York and Freehold Railroad, later absorbed by the Central RR of NJ. Harnley Road is an unimproved road closed to through traffic. The setting is wooded with several old abandoned outbuildings. The area has been used as a garbage dump. Parallel to the railroad tracks is an electric power line right-of-way.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span haunched timber stringer bridge has timber railings, timber deck, brick abutments with timber caps, and timber piers with timber caps, cross bracing, and brick footers. The timber is deteriorated and the bridge closed to traffic. In 1913 the bridge was built by the Central Railroad of New Jersey. It has been rebuilt and repaired in-kind. It is an example of a common bridge type, and is not associated with the historic period of the railway.

CONSTRUCTION DT 1907 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT DL&W RR OFFICE OF ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is contiguous to the Landing RR station in a commercial area. It carries a two-lane road sidewalks over active tracks of a commuter railroad and the abandoned Morris Canal R-O-W (National Register), filled and used as a parking lot. The NJ Cutoff connects with the main line about 1400' west of the bridge. The setting has lost its integrity due to alterations to the canal and station.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Historic District Status Unresolved.

CONSULT DOCUMENTS SHPO Finding 02/25/95

SUMMARY The two-span reinforced concrete deck arch bridge with a simple metal railing is technologically significant as a relatively early steel and concrete arch. It is also important for its historical associations with both the Morris Canal, still a navigable waterway when the bridge was built, and the DL&W Railroad, a leader in the use of concrete for bridges in the early 1900s. There is spalling on the east fascia and bowing on the west fascia.

INFOR MATION

Bibliography:
Lowenthal, L. & Greenberg, W. T., Jr. The Lackawanna Railroad in Northwest New Jersey. 1984.
Morris County Freeholders Minutes. June 8, 1887.

Physical Description: The 136'-long two-span concrete deck arch bridge adjacent to the Landing (Lake Hopatcong) passenger station is enclosed by a simple pipe railing that is original to 1907. The arch springs from about 10' above the ground. While the arches and west fascia have been gunited, there is severe spalling on the east fascia. The bridge crosses two active tracks of the Morristown Line and the abandoned Morris Canal right-of-way, now filled and used as a parking lot. On the north side, adjacent to the arch, are stone retaining walls while concrete retaining walls are on the south.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The bridge is the earliest earth-filled concrete deck arch in Morris County and the only two-span example of the bridge type in the county. It was designed and built in 1907 by Delaware Lackawanna & Western Railroad, a nationally recognized early leader in the use of concrete in bridge construction (Criterion C).

Although the 1907 multi-span bridge is just east of the National Register-listed 1912 Lake Hopatcong (Landing) station and about 1400 east of the junction of the New Jersey Cutoff with the DL&W's main line, it was built before either of those improvements were underway. In fact, it was constructed when the 1908-1911 New Jersey Cutoff was in the planning stage. Thus the Landing Road bridge ranks as one of the earliest documented reinforced concrete deck arch bridges built by the railroad in the state.

Landing was the major intermodal transfer station for the Lake Hopatcong vacation trade. The 1912 relocation of the station to the uphill or south side of the track required rebuilding the road and bridge into Landing. The station complex originally included a now non-extant concrete pedestrian bridge and access stairs from the station to the north side of the track and covered track side platforms.

The northern arch of the bridge crossed the Morris Canal during the active period of the waterway, which was abandoned in 1924. Although the canal has been filled and this section is used as a parking lot, the right-of-way is listed in the National Register in 1974.

Boundary Description and Justification: The bridge is first and foremost individually significant. It is located to the east of the National Register-listed Landing passenger station, and it crosses the National Register-listed right-of-way of the Morris Canal. Both listed resources have been significantly altered (the canal has been filled and the platform bridge and stair towers built as part of the station have been removed) thus altering the original context of the highway bridge. Because the setting has lost its integrity, the eligible boundary is limited to the span itself.

DESIGNER/PATENT DL&W RR OFFICE OF ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located behind the central business district and just north of a parallel bridge carrying the Boonton Line over the same features. The section of road is wooded and undeveloped due to the topography. The bridge is included in the Morris County Historic Sites Survey, which contains some misinformation about the abutments materials and construction dates. The bridge was constructed by the DL&W Railroad to provide a road between its two stations in Boonton.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 10/04/88

SUMMARY The steel bridge is composed of two riveted deck truss spans over the waterway and a shallower riveted deck plate girder span over the roadway. One of two similar bridges built by the DL&W RR, it is an unaltered example of an uncommon bridge type. It was constructed as part of the extension of Mossis Avenue to Main Street during a major improvement campaign. The original lattice railing is also well preserved. The SHPO has evaluated this and the other (1400082) as not eligible.

DESIGNER/PATENT CANTON BRIDGE COMPANY **BUILDER** CANTON BRIDGE COMPANY

SETTING / CONTEXT Spanning the headwaters of the Jersey City Reservoir, the bridge separates a wooded light industrial/commercial area of Parsippany Troy Hills Township from a dense residential area of Boonton Town. The bridge was part of a county improvement to provide a shorter route between Boonton and Morristown, prior to the construction of the reservoir. The Morris County Planning Board recognizes the bridge as a historic structure.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The deep, pin-connected deck truss bridge has had several modifications including concrete piers added in 1903 and numerous reinforcements and additions to the trusses beginning in 1909. The replacement of the northernmost span with two stringer spans in 1988 eliminated a difficult approach. The truss is historically significant due to its association with the boom years of Boonton. It is technologically distinctive because of its type and many of the alterations are historic changes.

"Bridge Building," The American Pictorial Monthly. June-July-August 1902.

Physical Description: The deep three-quarter deck truss bridge, originally built as a 5-span bridge with 4 deck truss spans and one short stringer or girder span on the north end, retains four of the pin-connected deck trusses. It is composed of built-up members with the top chords, inclined end posts, and verticals are toe-out channels with lacing and cover plates; a bottom chords are stamped eye bars. Sway bracing is round eye bar with turnbuckles. The diagonals and counters are stamped eye bars with turnbuckles. The truss was originally supported by stone abutments and steel bents.

The bridge, however, has been modified by a succession of additional members to strengthen the trusses and protect the piers from water damage when the reservoir was filled eight years after the bridge was constructed. Additions to the truss include a middle chord and knee braces for the floor beams, added in 1909, when the original plank deck was replaced with concrete; intermediate diagonals between the bottom and middle chord; and various riveted and bolted reinforcements. Additional diagonal tension members have been added to some panels. The riveted floor beams are apparently original, although the deck was replaced with metal deck pans on new steel stringers in 1958. Concrete piers, presumably cast around the original steel piers, were added by A. W. Edwards & Co., a local contractor, just before the reservoir was flooded in 1903.

The most significant alteration was the removal of the two northernmost spans (one deck truss and one stringer or multi girder) in 1987-1988 and replaced with two stringer spans supported by a concrete hammerhead piers to eliminate a difficult approach angle. A new concrete deck and various bolted repairs to strengthen weak truss members were made at that time. The 1988 rehabilitation was done in a sympathetic manner ensuring that the bridge would continue to function as a pin-connected span.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The 480' pin-connected Pratt deck truss bridge built in 1895 as a 5-span structure was considered a major accomplishment by the Canton Bridge Company. The bridge is one of two pin-connected deck truss highway bridges documented in the state making it a rare survivor of its type (Criterion C). The span has been modified quite a few times, but the work has been accomplished in a manner that has been sensitive to the original design and thus is not intrusive. The modifications do not detract from the technological significance of the span.

Modifications/alterations began as early as 1903, when the concrete piers were added to protect the structure from water and/or ice damage from the new reservoir. The bridge was previously supported on high built-up steel bents. At that time jurisdiction of the piers passed to the Jersey City Water Supply Company while the superstructure remained with the county. In 1909 the bottom chords, diagonals and pins were adjusted, and the mid-chords were added. That work was designed by noted civil engineer J.A. L. Waddell. The flooring system was done in 1958, but the original built-up floor beams were retained. In 1987-1988, the northernmost 2 span were removed and replaced with modern steel stringer spans on an improved realignment. Truss members were also repaired/strengthened at that time. The 1988 work was designed by A. G. Lichtenstein & Associates for Morris County. The numerous modifications/alterations have changed the trusses from a light, traditional Pratt structure to one of much heavier proportions. Despite the alterations, most of which are either historic changes or done in a manner that is sensitive to the original design and type, the bridge is technologically distinguished because of the rarity of its type, in the depth of the trusses, and the length of the spans. The south abutment and wingwalls are documented examples of the work of Theodore Ringlieb, a local stone mason who contracted for the stonework on numerous bridges in the county.

SETTING / CONTEXT The bridge is located in a mixed use area behind the central business district. Contiguous to the bridge are a playground and commercial/retail establishments, while low-income housing and a toxic waste site are in the immediate neighborhood. The mid-18th century Morristown business district was near the bridge, but relocated to the present site around the Green in the late 18th century. The bridge carries two lanes of traffic and two sidewalks over a major watercourse.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stone arch is the oldest continuously used bridge in Morristown, and is one of the oldest in the county. Built in 1822, it was widened with stone to the north ca. 1883 with the new portion at an angle to the original arches. The west sidewalk with its stone parapet is carried by the arch, while the 1928 east sidewalk is carried on steel stringers resting on random stone supports that obscure the arches. The original span has been so altered that is has little design integrity.

SETTING / CONTEXT The bridge is located in the center of Butler across from the ca. 1880 American Hard Rubber Company factory, converted to office use. The south side of the bridge is a mixed use commercial/residential area while the north end is located in the casually landscaped Butler Park which serves as a town green. Butler developed around the rubber industry, and it may have historic district potential. The bridge was built within the period of significance, but it is largely altered.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Historic District. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The ca. 1885 skewed stringer bridge with brick jack arches and an ashlar substructure is the only example of its type in the county, but it is one of at least 20 in northern New Jersey. It is has also been drastically altered, including ca. 1970 metal railings and gunite added to the underside in 1991. It does not retain its original/early appearance and thus does not contribute to the historic character of the potential historic district. Better examples of the bridge type remain in the region.

INFOR MATION

Bibliography:
Sanborn Insurance Atlas, Butler, N.J. 1901-1941.
Beers, F.W., Ellis, A.D., & Soule, G.G.. Atlas of Morris County, 1868.
Robinson, E. Robinson's Atlas of Morris County, 1887.
Salvini, E. Historic Bloomingdale. 1984.
"Board of Freeholders," The Jerseyman. June 10, 1887.

Physical Description: The steel stringer bridge with brick jack arches carries a wide roadway over a narrow brook with stone-lined banks. The bridge is on a large skew. The stone abutments are continuous with the stone-lined retaining walls which stretch for several hundred feet in both directions along the brook. Modern heavy gauge steel railings and a concrete brush curb are incompatible replacements for the original decorative lattice rail. The intrados was gunited in the summer of 1991.

Historical and Technological Significance: While date of construction remains undocumented, the bridge dates stylistically from the last quarter of the 19th century. It is likely the bridge at Butler near the rubber works mentioned in the minutes of the Board of Freeholders in June 1887 is this span. Sanborn Insurance maps of the town are conflicting and indicate that the bridge was never thoroughly surveyed by the company. The bridge dates from the growth years of the former American Hard Rubber Company and its predecessors, around which the village grew. The ca. 1880 brick factory building has been adapted for office use and is identified by a Morris County Historic Commission plaque. The development of the town to the east of Stone House Brook, including the establishment of schools, churches, a borough hall and firehouse, and substantial residential areas, occurred in the last quarter of the 19th century. The Butler Park, contiguous to the bridge is from this period.

The bridge is not a rare type, it has been altered significantly in recent years, and it does not retain integrity of original design. Nor does it contribute to the historic character of Butler. Although it lies in a potential historic district that includes the mill and other buildings in the village center, it is not a contributing resources because of its alterations and resulting modern appearance.

NAME & FEATURE INTERSECTED HAMBURG TURNPIKE (CR 694) OVER PEQUANNOCK RIVER **FACILITY** HAMBURG TURNPIKE (CR 694)

TOWNSHIP BUTLER BOROUGH

TYPE THRU GIRDER **DESIGN** **MATERIAL** Steel

 # SPANS 1 **LENGTH** 80 ft **WIDTH** 18.9 ft

CONSTRUCTION DT 1925 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is in Smiths Mills, an early-19th-century hamlet along the Paterson-Hamburg Turnpike, incorporated in 1806. The recently reactivated New York, Susquehanna & Western Railroad crosses at grade west of the bridge while a late-20th century home is located at the east end of the bridge. The bridge was part of the state highway project of the 1920s which utilized the Turnpike for part of Route 8. It carries a 2-lane rural road over a minor river.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The thru girder with floor beams bridge is supported on ashlar abutments with wingwalls that appear to date to 1875. The superstructure was constructed in 1925, by which time it was a common bridge type. This example is not technologically innovative or distinctive. The bridge is one of ten thru girder spans in the county.

CONSTRUCTION DT 1929 **ALTERATION DT** 1982 **SOURCE** COUNTY ENGINEER

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge is located at the end of the north end of the Butler business district where light industry has replaced the Pequannock Rubber Company mill which was destroyed by fire in the 1950s. The bridge crosses into Passaic County where Main Street forms a T-junction with the Paterson-Hamburg Turnpike (CR 694), lined with small commercial structures, some adapted from 20th century residences. it carries a wide 2-lane road and sidewalks over a minor river.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The box beam superstructure constructed in 1982 replaced the 1929 structure. Portions of the old concrete abutments and the center cutwater pier were reused. On the bridge, the steel balustrade consisting of three rails and posts is modern. However, the reinforced concrete balustrade on the south approaches dates from 1929. Because the span is primarily modern, it is evaluated as not historic based on its age and bridge type.

SETTING / CONTEXT The bridge is located in a wooded residential area of predominantly mid-20th-century dwellings. The area is the flood plain of the Pompton River. The bridge carries two lanes of traffic and one sidewalk over the river that serves as the boundary between Morris and Passaic counties.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The simply supported 2-span encased thru girder with floor beams bridge is supported on a concrete substructure and is representative of the other 5 similar spans in the county. The bridge type was used by both the state and the county in the 1920s & 1930s. The steel railing used at the cantilevered sidewalk is a design found on similar bridges from the same period, and while attractive, it is not unusual or unique. The span is not technologically innovative or historically noteworthy.

TOWNSHIP MOUNTAIN LAKES BOROUGH

TYPE SLAB **DESIGN** **MATERIAL** Reinforced Concrete

 # SPANS 1 **LENGTH** 22 ft **WIDTH** No Data

CONSTRUCTION DT 1936 **ALTERATION DT** **SOURCE** COUNTY ENGINEER

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in a wooded, low-density residential area started on a 1,000-acre tract in 1909. A series of seven spring-fed lakes are connected by a canal, over which the bridge carries two lanes of traffic and two sidewalks. The surrounding area is a well-preserved upper middle class planned pre-1930 neighborhood with architecturally significant houses, a school, church, and recreational buildings in a casually landscaped setting with common green spaces.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Potential Mountain Lakes Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY Finished with an arched-opening fieldstone spandrel wall, the skewed span is really a concrete slab designed to imitate an elliptical arch. It is one of 2 similar 1938 bridges built as amenities in Mountain Lakes, a 1909 subdivision developed as an exclusive residential enclave dominated by large, architecturally significant pre-World War I houses and related buildings, all in a park-like setting. The bridge contributes to a potential NR-eligible historic district. The bridge does not have the age, size, or distinctive detailing to be an individually eligible resource. While not individually eligible for listing in the National Register of Historic Places, the bridge would be a contributing element of a potential Mountain Lakes Historic District under Criteria A and C.

INFOR MATION

Bibliography:

The League of Women Voters of Mountain Lakes. This is Mountain Lakes. 1961-1989.
The Landmarks Committee Borough of Mountain Lakes, NJ. The Hapgood Houses of Mountain Lakes. 1983.

Physical Description:

Historical and Technological Significance: The slab bridge finished with cobblestone spandrel walls and parapets is a contributing feature in maintaining the original intent and historic development of Mountain Lakes, a planned suburb dating from 1911 (Criterion A). Masterminded and planned as an exclusive residential park by developer Herbert J. Hapgood, Mountain Lakes was laid out and improved to take advantage of the rustic natural beauty of the property. The subdivision plan included two manmade lakes interconnected by waterways that were adorned with bridges and stone work. The homes were to be placed on generous lots within the natural contours of the land, and they were to be in the Arts & Crafts mode. Key to the success of Hapgood's scheme was the rail link to New York City provided by the Erie-Lackawanna Railroad. The development was immensely popular, and by 1923, 600 homes and many amenities like a social club, community church, and stone walls and culverts had been built. Mountain Lakes became an independent borough in 1924. Remarkably, the original character of the community envisioned by Hapgood has been preserved making Mountain Lakes one of the best examples of a planned early-20th century upper class suburban community in the state.

While the bridge that carries Lake Drive over one of the interlake canals was not built in the initial phase of development (Hapgood went bankrupt in 1922), it was done in the original spirit of the development. It also reflects the intense desire and effort on the part of the community to continue the original development plan well after Hapgood's departure from the scene. The dedication to perpetuating and maintaining the original intent and thus the character of the development has marked the history of the community since the mid-1920s. The 1936 bridge reflects the original style and theme of the potential historic district in which it is located. While not individually distinguished from the technological perspective, the span is of historical significance to the community and the region.

Boundary Description and Justification: The bridge is a contributing resource in a historic district. Thus the span and its surroundings are evaluated as eligible. Defining the exact boundaries of the potential Mountain Lakes Historic District is beyond the scope of this survey.

DESIGNER/PATENT CORNELIUS VERMEULE **BUILDER** HYDE-MCFARLIN CONSTRUCT.

SETTING / CONTEXT The bridge is located in a wooded, mixed-use area at the end of the small Montville business district. It carries two lanes of traffic over a brook that flowed into the lower Montville inclined plane of the Morris Canal, the R-O-W of which is listed in the National Register. The bridge is part of the Morris Canal abandonment project of 1924-1927 where the state replaced timber truss bridges over the canal at locations where natural watercourses intersected the manmade waterway.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed encased stringer bridge has a concrete substructure and paneled parapets. The 23'-long span was built as part of the 1924 Morris Canal abandonment agreement between the State and the Lehigh Valley RR. Other more complicated bridges associated with the abandonment, completed under the direction of civil engineer Cornelius Vermeule, have been evaluated as historic because of their association with the project. This span was not based on its size and undistinguished technology.

SETTING / CONTEXT The bridge is located in the business district of Whippany, a village that developed in support of the paper industry, especially the Whippany Paper Board Company. The mills have closed, and, while some have been adapted to offices, most have disappeared. The bridge is between small businesses and a disused railroad.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Rubble-coursed stone abutments indicate that a bridge was here prior to the present 4-span continuous slab superstructure, but its type and date are not documented in the County Engineer's records. The bridge was widened to the east in 1963, but plans only document the addition, not what was in place in 1963. The cantilevered sidewalks are carried on encased stringers, and they are enclosed by a metal fence-like railing. The slab bridge is historically and technologically undistinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** ANDREW JACKSON TUERS

SETTING / CONTEXT The bridge is located in a mixed-use area of mid- to late- 20th century housing developments. Adjacent to the bridge is a modern firehouse. The structure is inventoried in the Morris County Historical Commission's Historic Sites Survey of1986-1987. It carries two lanes of traffic and two sidewalks over a minor watercourse.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span random ashlar stone bridge was widened on both sides with concrete slabs in 1965. While the stone parapets have been rebuilt and the original builder's plaque included in the west parapet, concrete replaces the original cap stones, and the stonework has been insensitively repointed. The bridge has little integrity and is not in a potential historic district. Other stone arches in Morristown and Mt. Arlington (1400855) are better technical examples and more historically important.

SETTING / CONTEXT The bridge carries a 2-lane street and sidewalks over a river at the line between Morris and Passaic counties. The Morris side is a mix of modern industrial and late-19th century residential while the Passaic side is industrial and wooded. The river banks is known to have been the site of a paper board mill during the 19th century, but no above-ground mill buildings remain.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The handsome elliptical arch with attenuated proportions is the best example of its type in the county. Neither the earliest nor the longest, the bridge is the most architectonic and ambitious of the eight similar concrete arches. Built as a joint-county project, the well-detailed span is an excellent example of the City Beautiful movement. The unaltered bridge is highlighted by urn-shaped balustrades. It is significant as a fine example of the well-detailed joint-county spans in the area.

INFOR MATION

Bibliography:
Robinson, E. Robinson's Atlas of Morris County. 1887.
"Bridge Notice," The Jerseyman, July 9, 1886.
Cunningham, J. Chatham at the Crossing of the Fishawack.

Physical Description: The handsome and well-proportioned elliptical concrete deck arch bridge is a well-preserved example of its type and style. The arch springs from near the water line in a low elliptical curve. The closed spandrel panels are picked out with incising. Balustrades of reinforced concrete with classically-inspired urn-shaped balusters between paneled rectangular posts continue into the splayed approaches. The balustrade design is one of the most decorative and least altered found on any of the nine concrete deck arches in the county built between 1907 and 1944.

Historical and Technological Significance: Historically known as Edwards Mill Bridge because it is located at the crossing adjacent to the non-extant 19th-century mill, the bridge is the most significant local example of the handsome reinforced concrete deck arch bridges that were frequently used on county boundaries in the 1910s and 1920s. With its elegant balustrades and attenuated proportions, the bridge is more architectonic than most other concrete deck arches in the county. It is also a well-preserved example of a bridge type that was immensely popular during the same period, and it represents the application of aesthetic considerations to civic improvements that is the hallmark of the City Beautiful movement (Criterion C). Plaques on both ends of the bridge document that it was funded by both Union and Morris Counties and was designed by Frederick S, Smith, the Morris County Engineer and Jacob Bauer, the Union County Engineer.

Boundary Description & Justification: Because the bridge is evaluated as individually distinguished, the boundary is limited to the structure itself. The surrounding area does not appear to have historic district potential.

SETTING / CONTEXT The bridge is located within the Passaic River Park at the boundary of Union and Morris Counties. The park is used for hiking and fishing on the Union County side while the Morris County side is wooded, with a 1980 condominium complex abutting the river.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The steel thru girder bridge is supported on stone masonry abutments and caisson-like concrete piers with built-up metal jackets. The rolled section floor beams are replacements and are not located in the position of the originals. When they were installed is not known. Other alterations include an open grid deck (1974) (original was concrete) and gunited masonry (1989). Two other bridges in Morris County from the 1890s (1400976, 1401021) have the same caisson-like piers. Information on the bridge is scanty. The superstructure has been greatly altered. The piers alone, which are found on earlier county bridges with design integrity, do not make the spans significant.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in a wooded low-density residential area with scattered homes from the 19th century to present. The bridge carries two lanes of traffic over a watercourse that is trout-stocked and posted for recreational use.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The elliptical reinforced concrete deck arch span is one of over 9 similar county bridges built between 1911 and 1944. Ornamentation is limited to incised panels in the spandrels. Although it retains a pipe railing, it is an undistinguished representative example of its bridge type. Examples, like 1400514, with more elaborate detailing exist in the county. This bridge is not historically or technologically distinguished.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-proportioned reinforced concrete deck arch bridge is finished with a distinctive lattice-panel concrete balustrade. It is a representative example of the well-detailed concrete deck arch spans built over the Passaic River by Morris, Passaic, Somerset, and Union counties in the 1910s and 1920s. The balustrade has numerous repairs. The bridge is not technologically distinctive, and more significant examples are 1400514 and 122B135.

SETTING / CONTEXT The bridge is located at the southwest corner of the Great Swamp National Wildlife Refuge, a 7,200 acre wetland area. It is also contiguous to the Lord Sterling Park, a rural park maintained by the Somerset County Park Commission. An 18th-century farmhouse with outbuildings is to the southeast of the bridge, which carries one lane of traffic and a sidewalk over a major watercourse. The bridge is casually mentioned but not inventoried in the Morris County Historic Sites Survey.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The Warren pony truss constructed of riveted back-to-back angles received a major rehabilitation in 1952 consisting of the addition of 15" channel welded to the top chord, welded angles added to various diagonals, outriggers, and a cantilevered sidewalk. The bridge is supported by steel columns welded to the bottom chord at all four bearing locations. The alterations compromise the design integrity of the structure and make it an undistinguished example of its type.

SETTING / CONTEXT The bridge is located next to the picturesque Pleasant Valley Farm with an 18th-century farmhouse, barns, and outbuildings adjacent to the bridge. The Morris County Historic Sites Survey notes the "beautiful views and pastoral setting" and casually mentions the bridge. Throughout the first half of the 20th century the farm was owned by former state senator Arthur Whitney.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Ralston Historic District. 02/20/1975. Contributing.

CONSULT DOCUMENTS SHPO Technical Assistance Letter 12/15/93.

SUMMARY The welded Pratt pony truss bridge is constructed of steel I-beams and channels with gusset plates at the connections. County records indicate that it was built for this crossing in 1934, but the stone substructure is earlier. It is well preserved with the only repair being replacement of one stringer in 1984. The bridge is technologically significant as an early example of a new technology; welding for all shop and field connections. It is one of the earliest all welded bridges in the state.

Hess, Jeffrey. Benton Street Bridge (Iowa City, Iowa). HAER Report IA-30; 1989.

Physical Description: The 5-panel, 56'-long Pratt-type pony truss span is composed of rolled I- and channel-sections, and it is distinguished by the fact that it is totally welded. It is supported on rubble-coursed fieldstone abutments that predate this superstructure. Knee braces or outriggers are set on the outside of each truss, and the inner face is protected by plain metal railings welded to the trusses. The bridge appears to be unaltered with repairs being inkind rather than modifications to the original design.

Historical and Technological Significance: The 1934 truss bridge on Roxiticus Road ranks as one of the earliest all-welded pony truss spans in the state. It is technologically noteworthy because it is an early example of its type and represents the transition from riveted to welded connections in the bridge building (Criterion C). Because of its date of erection and state of preservation, the Roxiticus Road span was evaluated as the noteworthy example of the approximately one dozen welded pony truss bridges from the 1930s in the state.

Welded bridges appeared in the United States in the 1920s, but welding was not widely advocated for new bridge construction until immediately after World War II. Electric arch welding began in Europe in the 1880s. The first commercial welding in this country is thought to have been done by Baldwin Locomotive in 1902. It was used successfully during World War I to quickly repair and return confiscated German ships to war service, and after the war welding became a common fabrication practice in heavy industry. The building industry, however, was more cautious in embracing welding. General Electric and Westinghouse Electric both built welded structures in the 1920s. Westinghouse, in particular, was interested in showcasing any new technology allied with electricity, so the company was a leading proponent of electric-arc welding.

The first all-welded highway bridge was a traditional camelback pony truss bridge built in Poland in 1929. Its designer heralded the span as a great saver of material because the design required less steel to produce rigid joints than a riveted truss. Although welding became a common repair technique for bridges during the 1930s, its application to new construction was quite limited, especially in the United States. Of the approximately 1,000 pre-World War II welded bridges in the world, very few were of them were located in this country. But, rather than following Europeans' lead and experimenting with welded bridge designs, Americans tended to follow "the beaten path of riveted construction, the thought being that welding was replacing riveting." The Riverside bridge reflects well the pre-war thinking about all-welded bridges in this country.

During World War II welding came into its own as anything that could be welded together was. By 1945, it was the most important method of joining steel, and after the war all-welded bridges became the norm rather than the exception. Thus, the Riverside bridge stands as a record of the cautious American transition from riveted to welded bridges. Its technological and historical significance is enhanced by the fact that the bridge and its operating mechanism survive in a remarkably complete state of preservation.

Boundary Description and Justification: The bridge is individually significant on its own merits, and the boundary is limited to the bridge itself (superstructure and substructure including any wingwalls).

SETTING / CONTEXT The one-lane bridge is located in a wooded section on a county road that serves as a by-pass for a state highway. It is approximately ten feet below the stepped ashlar stone dam of Lake Openaki, a small private lake. Adjacent to the bridge is a well-maintained 18th-century dwelling. The southbound traffic that approaches the bridge on a bad curve has the right-of-way over the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY One of 10 pin-connected truss bridges in Morris county, the 3-panel half-hip Pratt pony truss bridge is the only county example of the Dover Boiler Works, a local fabricator active in the early 20th century. The fact that it is a locally made bridge is significant. While the span has been strengthened with pier bents on concrete pads, it has few welded repairs and retains its integrity. It also has all four maker plates, two cast-iron ball finials, and the bridge committee plaque.

INFORMATION

SOURCES:
Morris County Engineer's Office. Bridge File.
Darnell, Victor C. Directory of American Bridge-Building Companies 1840-1900. 1984.
Platt, Charles D. Dover Dates. 1922.
Morris County Freeholders Minutes, 1903-1907, 1934.
Kelly, Robert. Telephone conversation with B. Riley. 24 November 1991. (201-361-6026).

Physical Description: The 3-panel pin-connected half hip Pratt pony truss is a relatively complete example of its type. The top chord and inclined end posts are composed of channels with riveted cover plates while verticals are toe-in angles joined by lattice. Diagonals are pairs of 2" round bars with loop forged eyes, and turnbuckles are used in the middle panel only. The bottom chord is made up of drop-forged eye rods. Welded gusset plates have been added at the top and bottom panel points. The built-up riveted floor beams appear to be original, but they are strengthened by rolled I-beams placed below the original floor beams. Both beams are connected to the panel point by U-bolts. Strengthening knee braces were welded on the north verticals but not to the ones on the south end. Steel bents on a continuous concrete footing were added near the abutments and at the interior panel point in 1951, changing the bridge from a one-span to a 5-span structure. The 1975 asphalt-filled corrugated metal deck is a replacement for a plank floor. While a channel curb has been added to protect the truss members, the riveted lattice rail is apparently original to the structure.

Cast-iron plates are at each of the four corners identify the fabricator, with two on the west side retaining the ball finials. On the west side is a cast plaque bearing the date and names of the bridge committee members.

Abutments and wingwalls are stone, presumably built for the current bridge, as in most Morris County metal bridges. Gabions were added on the north end of the bridge in 1980.

Historical and Technological Significance: The Pratt half-hip pony truss bridge is significant in that it is the only Morris County example of a truss bridge by a local fabricator, the Dover Boiler Works. Dover Boiler Works was started in 1874 as a small repair shop doing hand repair work. It grow "into the largest and best equipped contract Plate Work Shop in the New York District and possibly the entire east" (Platt, p. 233). They manufactured a general line of steel plate work such as tanks, stand pipes, stills, dryers, bins, and steel shapes and plate like angles, channels, rivets, blots, and castings. The products were fabricated from materials secured from major steel mills in Pennsylvania and marketed for industrial use worldwide.

The company was established in 1874 by the Foster F. Birch who was succeeded by his son William F. Birch, who was active in national politics. It went into receivership in 1934 and the plant was destroyed by fire in 1935. While it is uncertain how important bridge fabrication was to the company, Dover Boiler Works was a major contractor for bridge repairs in Morris County from the early 1900s the company's end in the 1930s. The company also constructed stringer bridges throughout the county during this period.

Bridges fabricated by Dover Boiler Works have been identified in Somerset and Hunterdon Counties. Their 1903 Griggstown Causeway (18F0302) in Somerset County has numerous welded reinforcements that have compromised its integrity, but noteworthy examples of the work of the company that date to as late as 1919 are in place in Hunterdon County.

SETTING / CONTEXT The bridge is in a wooded setting in an undeveloped section of the township. The Patriot's Path, a public footpath maintained by the Morris County Park Commission and traversing the southern part of Morris County, is adjacent to the bridge. The crossing predates the current bridge as evidenced by the stone wingwalls and abutments. The bridge carries two lanes of traffic over the meandering Whippany River.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The short steel stringer bridge is supported on stone abutments with wingwalls that predate the superstructure. The bridge seats are concrete, and they were added when the stringers were installed in 1944. The simple railing is composed of channels, and it contributes to maintaining the rural character of the area. Overall, the bridge is a representative example of the over 50 stringer spans in the county, and it is not historically or technologically distinguished.

SETTING / CONTEXT The bridge is located in a wooded setting and crosses the headwaters of Speedwell Lake. It is situated between the former right-of-way of the Rockaway Valley (Rockabye Baby) Railroad and a second bridge over the lake. The Patriot's Path, a public footpath maintained by the Morris County Park Commission, crosses the lake on the bridge. The structure is within the Historic Speedwell Historic District boundaries, but is a non-contributing structure based on its date of construction.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Not Individually Eligible. Listed. Historic Speedwell Historic District. 11/13/1986. Noncontributed.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The elliptical concrete deck arch bridge built in 1944 incorporates the stone wing walls from previous span at what has been a crossing since at least the mid-19th century. The arch, with a pipe railing, is the latest of the 10 deck arches built in the county between 1911 and 1944. It has been altered by the addition of a sidewalk. The span is outside the period of significance of the historic district and is evaluated as not having historical or technological significance.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is in a wooded area at the head of Speedwell Lake, within the Historic Speedwell Historic District (National Register), a 19-th century industrial complex which used the lake as a power source. To the south is a 1944 concrete arch bridge and to the north is a nondescript 1950s residence and the former town dump, now used as a recycling center. With two lanes of traffic the bridge also carries a sidewalk for the Patriot's Path, a footpath maintained by the county.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Not Individually Eligible. Listed. Historic Speedwell Historic District. 11/13/1986. Noncontributed.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The short bridge is constructed of rolled steel stringers with steel angles riveted to the to web. The bridge was built during World War II with stringers apparently reused from a another structure. Stone masonry abutments and wingwalls predate the superstructure. The white pipe railing is common among rural bridges. The superstructure is technologically undistinguished, and it was built after the period of significance of the Historic Speedwell Historic District so is thus non-contributing.

DESIGNER/PATENT UNKNOWN **BUILDER** THOMAS J. ALLEN

SETTING / CONTEXT The Glen Bridge is located in a wooded residential area on a busy connector road. Contiguous to the bridge is Tanglewood Glen Park, a wooded parkland created in the late 1880s when Mt. Arlington was being developed as a summer resort. While well outside the Mt. Arlington Historic District (National Register), the bridge is listed in the MCHC Historic Sites Survey, with comment on the late-19th-century combination of the picturesque and utility.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Construction of the handsome barrel arch with stepped wingwalls was one of first public works projects in the newly formed borough of Mt. Arlington. The rusticated stonework and date in the keystone are similar to the Speedwell Bridge (1416152), by the same contractor. However, the setting, unique wingwalls, and relationship to the park and community, make the bridge historic in its own right. It is one of the few bridges in the county with an elevation in clear view from a public road.

INFOR MATION

Bibliography:
Robinson, E. Robinson's Atlas of Morris County. 1887.
Guter, R. Morris County Historic Sites Survey. 1986.

Physical Description: A well-proportioned barrel stone arch bridge that spans a small glen at the lower edge of a wooded public park, the span is virtually unnoticeable from the roadway. However, from a lower branch road there is an unobstructed view of the north elevation through a private land where the small stream of Windermere Brook flows. The random-coursed, rusticated stone barrel arch bridge with square voussoirs has flared stepped wingwalls. Both the span and the wingwalls are capped with large, rusticated granite slabs. On the inside faces of the parapets are stone tablets documenting the incorporation of the borough and the bridge commissioners. The date of construction is also cut into the keystones.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The well-proportioned span is one of the aesthetically most pleasing examples of a stone arch bridge technology in the county. It was built as a civic amenity in an area of the county developed in the postbellum period as a summer resort for the wealthy, who arrived mainly by train and lake steamer. The bridge location, at the bottom of Tanglewood Glen Park, was between the North Park with its two hotels and large private residences, and the South Park, being developed as private residences. Tanglewood Glen Park, a wooded park with footpaths, served as a recreation area between the two major residential areas and continues to remain a public park.

With no alterations, the bridge is significant as an example of local stonework combining the picturesque with the functional purpose of spanning a small ravine. It is also representative the grand era of Lake Hopatcong resort hotels and the development of Mt. Arlington as a planned community that catered to the wealthy New York seasonal trade. While none of the hotels are have survived, a section of the single family houses remains, and it comprised the National Register-listed Mount Arlington North Park Historic District. The bridge is not within on the boundaries of the district.

Boundary Description and Justification: Because the bridge is individually significant, it is the span itself and its wingwalls that define the limits of the eligible resource.

SETTING / CONTEXT Located at the end of Main Street in Rockaway, the bridge is a transition from the commercial center to a residential neighborhood. The area has mainly 19th-century structures, but some modern intrusions exists at the west end of the bridge. Just upstream is the dam for the forge and grist mill, both nonextant, owned by the Jackson and Halsey families during most of the 19th century.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1840 well-proportioned 3-span stone arch bridge is reasonably well preserved on the east side which is finished with voussoirs. The west side was widened with concrete in 1905, but it retains the lines of the arches. A steel stringer sidewalk on east side dates to 1890 and is supported on stone abutments and steel caissons. It is a significant detail as is the survival of the lattice railing with cast-iron posts. The bridge is significant as an early stone arch span and for the caissons.

INFORMATION

Bibliography:
Beers, F.W., Ellis, A.D., & Soule, G.G. Atlas of Morris County. 1868.
Robinson. Robinson's Atlas of Morris County. 1887.
L. Lowenthal and W. T. Greenberg, Jr. Morris County Traction Company. 1984.
Morris County Freeholders Minutes. July 9, 1890, October 11, 1905.
Rockaway Borough Bicentennial Committee. Rockaway Borough, A History. 1976.

Physical Description: The well-proportioned 3-span elliptical stone arch bridge is constructed of rubble-coursed local stone. The arches spring from near the water line and are finished with ring stones. The width of the span was nearly doubled in 1905 with a concrete extension on the west side. The intrados of the arches have been gunited. A sidewalk on separate, continuously supported stringers on the east side was constructed added by the Riverside Bridge Company in 1890. It is supported by caissons-like concrete piers with built-up metal jackets that are aligned with the arch spandrels. The lattice railings retain some nice cast iron posts. Date of their installation is not known, but stylistically it appears to also date to the 1890s or 1900s.

The bridge carries the former Newark and Mount Pleasant Turnpike, chartered in 1806, over the Rockaway River at a point between the upper and lower mill ponds. Both dams are still extant, while the iron mills have been adapted to lighter industrial uses. The area does not retain its 19th century character and thus does not have historic district potential. There are numerous 20th-century intrusions.

Historical and Technological Significance: Although the original date of construction and the contractor of the 3-span stone arch bridge are unknown, the span appears to date to ca. 1840, Rockaway's proto-industrial era that was dominated by water-powered forging and rolling industries. The ca. 1840 bridge is one of the more complete early stone arch bridges in the county. Two modifications to the span, the 1905 widened with a concrete extension to accommodate the Morris County Traction Company's operation and the 1890 installation of a sidewalk supported on caisson-type built-up metal jacket piers, are technologically significant details in their own right, and they contribute to the technological importance of the bridge (Criterion C).

The 1890 stringer sidewalk on supported on caissons-like concrete-filled piers with built-up metal jackets was built by the Riverside Bridge Company of Paterson, NJ. This sidewalk arrangement is one of two such surviving examples in Morris County. The other sidewalk supported on caisson-like piers is at the North Sussex Street bridge over the Rockaway River in Dover (1401021), and it to was built by the Riverside Bridge Company in 1886. Each sidewalk was built to provide safe pedestrian passage at a 3-span stone arch in a busy industrial center. The caisson-like piers supporting the stringer sidewalk contributes to the technological significance of the bridge.

The widening of the bridge in 1905 was one of early improvements made by the Morris County Traction Company, an electric street railway, in its 10-year (1904-1914) effort to complete its line between Elizabeth and Lake Hopatcong. The traction company was responsible for the design and expense of the widening, but plans were to be approved by the Morris County Engineer. The widening was accomplished with a concrete span, making it one of the earliest extant uses of the then-new material in the county. The trolley ran on the new, concrete portion on the west side of the bridge.

Boundary Justification and Description: Because the bridge is individually distinguished, the boundary is limited to the span itself. The surrounding area contains some significant structures, but it does not have the integrity to be evaluated as a historic district.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed steel stringer bridge built in 1925 on a concrete substructure has been heavily altered. It was widened in 1966, and then strengthened in 1977 when new I-beams were placed between the existing stringers. Modern heavy gauge pipe railings replace the original. The integrity of the original design has been lost as has its historical and technological significance. The bridge is one of over fifty stringer spans built before World War II that survive in Morris County.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located one-half block off the main business street and is situated between commercial warehouses and a late-19th church with a little design integrity. It carries a 2-lane street over the river, which is paralleled by a disused railroad right-of-way. The river is a main feature in Dover. The area does not have National Register historic district potential.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The elliptical concrete deck arch bridge is one of 11 in the county, and it is one of the most altered of the group. A modern steel pipe rail set in I-section posts in a low concrete parapet replaces the original railing, and the arch has been gunited. As a result of the modifications, the span has little design integrity. A more complete example of this bridge type is Summit Avenue in Chatham (1400514).

SETTING / CONTEXT The bridge is the within Blackwell Street Historic District (National Register) where it is an undetermined resource. Adjacent to the bridge are late 19th- and early 20th-century commercial buildings. A one-story structure faced with eclectic-styled pressed metal siding is cantilevered over the northeast arch of the bridge. During the mid-19th century a steel furnace stood at this corner of the bridge and the Morris Canal crossed the Rockaway River just east of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. Blackwell Street Historic District. 05/21/1982. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span stone arch bridge of coursed random ashlar and sandstone voussoirs dates to 1825, and it is historically associated with the Morris Canal & Banking Company. It is thus a contributing resource to the historic district. Although altered several times (west sidewalk carried on caissons added in 1886: east cantilevered sidewalk and concrete balustrades added in 1938), the original arches are discernible. The span appears to be the oldest documented stone arch bridge in the county.

INFOR MATION

Bibliography:

Sanborn Insurance Map of Dover. 1886, 1890, 1896.

Physical Description: The 35'-wide three-span stone arch bridge of local, coursed ashlar stone with red sandstone voussoirs was originally constructed in 1825 to carry two lanes of traffic. The west sidewalk, a separate stringer structure supported on concrete-filled riveted metal caissons, was added in 1886. The sidewalk was built by the Riverside Bridge Company, and the caissons are aligned with the mid-stream arch spandrels. The east sidewalk, a single-span stringer, is a 1938 replacement for an earlier sidewalk from which stonework pads for piers remain on the downstream side at the intermediate bases of the arches. The stone arch bridge and the two wide sidewalks appear as a unified whole from the roadway because of the 1938 reinforced concrete balustrades with rectangular piercing and plain pylons which form matching barriers on both sidewalks.

Historical and Technological Significance: The three-span stone arch bridge on North Sussex Street, the oldest surviving bridge in Dover, is located within the National Register-listed Blackwell Street Historic District which is recognized as significant in the area of transportation. Dover is a commercial center that grew around the water power of the Rockaway River, the abundant iron in the surrounding hills, and the transportation base of the Morris Canal. The bridge was built in 1825 by local contractors for the Morris Canal & Banking Company, builder of the Morris Canal which was complete here in 1826. The bridge is unrated in the 1982 National Register nomination, but it is evaluated as a contributing resource to the district based on its historical associations, date of construction, and state of preservation (Criterion C).

The first stretch of the canal to open in 1826 was the four-mile stretch between Dover and Rockaway. That section used water from the Rockaway River. Just east of North Sussex Street, the canal crossed the Rockaway River, passing through guard locks at each side of the river. At this time the old turnpike bridge on what is now Warren Street, west of North Sussex Street, was abandoned and North Sussex Street became the only river crossing in Dover.

While the stone arch is not technologically innovative, being used for centuries prior, the significance of the North Sussex Street Bridge is that its construction coincides with the birth of Dover as an industrial and commercial center. Before the Morris Canal, Dover was a hamlet with less than a dozen houses. But with a sizeable iron industry built along the Rockaway River and using charcoal as fuel, by the middle of the 19th century, only twenty-five years after the opening of the canal, Dover had become one of the four largest towns in Morris County. It remains a major commercial and population center.

Also of significance is the 1886 stringer sidewalk, which was debated heavily by the Board of Freeholders for several months. Several members did not feel that the Board was responsible for providing and maintaining footbridges. However, due to the heavy industrial traffic on the bridge, the Board voted in favor of pedestrian safety. The sidewalk is supported on caisson-type concrete piles with built-up metal jackets, an unusual detail that is found on one other bridge from the same period in Morris County (1400976). At that bridge, which carries E. Main Street over the Rockaway River in Rockaway Township, the caisson-type pile are also used to support a sidewalk.

Boundary Description & Justification: The bridge is located within a National Register-listed historic district, so it is surrounded by contributing resources. The bridge too contributes to the historic character of the district.

SETTING / CONTEXT Located at a T-junction, the bridge is in a heavily wooded section of the township with no structures in the immediate vicinity. Throughout the second half of the 19th century, the home of Louis B. Stephens, now non-extant, stood next to the bridge. An enclave of Stephens families lived just downstream, and they used the stream's water power for saw and grist mills. Members of the family carved their names in the capstones, one leaving the date "July 13, 1883."

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The rubble-coursed fieldstone arch bridge with ringstones and corresponding stone parapets is one of two 2-span stone arches spans in the county (1401250). It has not been widened, but the intrados of each span has been gunited. The original cap stones have been replaced with concrete on the west side. Major character defining features such as the arch forms, the stone parapets, and the stone wing walls retain integrity. The structure is individually eligible for listing in the National Register of Historic Places under Criterion C as a representative example of stone arch bridge technology.

SETTING / CONTEXT The bridge is a contributing resource within the Four Bridges Historic District, recognized by the Morris County Planning Board. Contiguous to the bridge is Sharp's Mill, a working water powered grist mill when the bridge was built and well into the 20th century. The bridge is below the mill dam, while in the immediate area are four early 19th-century houses and a large barn, all of which are contributing resources in the district. The one-lane bridge carries a connector road.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Historic District Status Unresolved.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel pin-connected half-hip Pratt pony truss bridge, one of 9 in the county, has lost its integrity of design. It was shored up with a center steel pier bent (1963). Other major alterations include welded strengthening to the lower portion of the verticals and steel channel to the upper chord. These alterations change the characteristics of the bridge. The stone abutments have been gunited. The original lattice railings remain. Alterations make the span technologically undistinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in a wooded rural setting contiguous to a farm with an early 20th century farmhouse and scattered outbuildings in poor condition. It is itemized in the Stephensburg Historic District, recognized by the Morris County Heritage Commission and the county Planning Board. The district is a densely developed hamlet containing a mill, dwellings, barns, and outbuildings from the mid-19th century. The bridge carries one lane of traffic across a minor watercourse.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Historic District Status Unresolved.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Originally a single-span stringer bridge on ashlar abutments, it was changed to a 2-span bridge by the mid-20th century addition of a mid-span pier composed of concrete columns and a steel cap beam. The stone abutments and wingwalls have been capped and gunited. The most distinguishing feature are the lattice railings with some of the original well-detailed cast-iron posts. While the railings are noteworthy, the span itself is not technologically innovative nor an early example of its type.

SETTING / CONTEXT The bridge is located in the heart of the German Valley Historic District comprised of 76 residential, industrial, commercial, and public buildings dating from the late 18th through the early 20th centuries. The bridge is inventoried as a contributing structure to the district. It carries a narrow two-lane road over a major watercourse.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Listed. German Valley Historic District. 07/14/1983. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The random-coursed stone elliptical arch bridge with a slight vertical profile is characteristic of the stonework that is strongly associated with the German Valley area. It is the longest and only 4-span stone arch bridge in the county. The west side is the better preserved with its low parapet with capstones. Alterations to the east side include a concrete replacement parapet, steel guiderail, and a steel stringer sidewalk installed in 1976. However, the integrity of the bridge survives.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in a bucolic 19th-century village setting on an unpaved road bordering Black River Park, an undeveloped county park. A 3 1/2-story stone grist mill is at the northwest corner of the bridge and the mill's tail race passes under one of its spans. The bridge is a contributing structure in the Lower Hacklebarney Historic District, recognized by the Morris County Heritage Commission. The district has National Register potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stone arch bridge with arches of unequal dimensions is the only surviving bridge in the county built to accommodate a tail race. The ca. 1830 stone grist mill abuts the northwest wingwall of the bridge. The bridge is well preserved, save for gunited intrados. The original 4" slate capstones with "iron staples" finish the parapets. The mill and bridge are individually distinguished because of their age and condition, and they are significant elements in a potential historic district.

INFOR MATION

Bibliography:
Guter, R. Morris County Historic Sites Survey. 1986.
Greenidge, F. Chester, New Jersey, A Scrapbook of History. 1974.

Physical Description: The 2-span rubble-coursed with ring stones stone arch bridge is part of a picturesque 19th-century hamlet that grew around the water power provided by the Black River. The 21'-long main span of the bridge accommodates the river while a smaller span of approximately 10' crosses the mill tail race. The ca. 1830 rubble-coursed stone mill forms the northwest wingwall of the bridge. The parapets are of linearly varying height, to a maximum of 3' in the center and diminishing to grade level at the ends. Capstones of 4" slate are connected with iron staples. The southwest parapet is tied into a retaining wall at right angles to the bridge along the west bank of the river.

The intrados of each arch was gunited in 1981.

The integrity of setting that the bridge enjoys is remarkable, and it contributes greatly to the significance of the structure.

Historical and Technological Significance: The undocumented ca. 1830 2-span stone arch bridge is an integral part of the bucolic hamlet of Lower Hacklebarney with its early 19th-century houses, ca. 1830 stone grist mill to which the bridge is contiguous, stone dam, and mill pond. While the mill and bridge are individually significant as well-preserved examples of their structural types, made all the more significant because they were, it is believed, built and worked in tandem, they are also contributing structures in a larger context; the well-preserved nuclear village (Criterion C). The settlement, composed of seven (7) structures, is a good representative example of the small population centers that developed around water-powered mills in the early and middle 19th century. The type and style of buildings clearly reflect the economic basis for the settlement. The architectural significance of lower Hacklebarney is enhanced by the picturesque quality of its unspoiled setting.

While the technology reflected in the stone arch bridge is not innovative for ca. 1830, the incorporation of the a span into the grist mill structure is not common. The mill shows no alterations or additions, but the arches of the bridge were gunited, and the spandrel walls were repointed in a sensitive manner. The dirt road is paved over the deck of the bridge. The bridge ranks as one of the several historically significant stone arch span in Morris County, which has a strong stone arch bridge tradition. It is evaluated as a noteworthy example of the bridge type, in part, because of its physical and historical connection with the mill and the surrounding village.

Boundary Description and Justification: The bridge is one element in an architecturally significant setting that appears to meet the criteria for inclusion in the National Register as a historic district. Thus the bridge, its wingwalls, contiguous stone grist mill and surrounding land are evaluated as significant. Defining the boundaries of the potential historic district are beyond the scope of this survey.

SETTING / CONTEXT The bridge is located in a wooded area of overgrown farmland. Adjacent to the bridge is a one-and-a-half story early- to mid-19th-century farmhouse reworked to appear Victorian. The bridge carries a single lane of a rural road over a trout-stocked river which forms the boundary of Morris and Somerset Counties.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-panel pin-connected half-hip Pratt pony truss bridge, one of over 10 in the county, has been altered significantly by welded members added mid-century to strengthen the trusses. They include diagonals, gusset plates at the panel points, and cover plate welded to the verticals and top chords. The span no longer functions as a pin-connected bridge and has lost its design integrity. It is neither historically nor technologically significant due to the alterations.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge is located on a state highway, just east of the boundary with Warren County. To the east is undeveloped woodland while undistinguished commercial structures are to the west. The bridge carries two lanes of traffic and one sidewalk over a minor watercourse that flows out of a penstock just north of the highway. The bridge was part of the state highway project of the 1920s, carrying Route 5 over a mill race. The mill is nonextant.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased stringer bridge with a concrete substructure and concrete balustrades set between plain posts incised with the date and route number is a representative example of its structural type. It is one of over 50 stringer spans in Morris County, and it has no distinguishing historical or technological features.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge is located in a commercial area of a state highway. Carrying two lanes of eastbound traffic, it was built as part of the state highway project for Route 5. A new bridge separated by a grass median but on common abutments carries the westbound lanes.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The short stringer bridge with a concrete balustrade set between plain posts incised with the date and highway number has been altered. The south side balustrade was demolished when the roadway was expanded from two to four lanes and a parallel west-bound right of way with a median was built in 1984. The west-bound addition is listed as a separate bridge. The altered bridge is not historically or technologically noteworthy. It is one of over 50 stringer spans in the county.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge is located in a sparsely developed section of a state highway where the eastbound and west bound lanes are separated by a wide wooded median. A modern veterinary clinic is located in the median east of the bridge and a single residential building is on the south side of the highway. The bridge carries two lanes of eastbound traffic over a minor watercourse.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed encased stringer bridge on a concrete substructure bears little resemblance to its original design. The Jersey-barrier like parapets on both sides with steel guiderail bolted to the inside face replace the original balustrade. The short bridge has lost its integrity of design. While the original encased stringers and substructure are intact, the modifications render the span, an example of a common pre-World War II bridge type, historically and technologically undistinguished.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The skewed brick arch bridge has handsome dressed ashlar spandrel walls and ring stones. The intrados was gunited, but much of it has spalled. The bridge was widened on the downstream side about 20' in 1922, but the concrete extension was finished with a matching ashlar spandrel wall. Despite the alteration, the original section is relatively well preserved and ranks as one of the largest and most impressive brick arch spans in the state. It is evaluated as technologically significant, and is individually eligible for listing in the National Register of Historic Places under Criterion C. It is also a contributing element to the National Register listed Speedwell Village Historic District.

INFOR MATION

ONJH. National Register File: Morristown Multiple Resource Nomination, 1983.

Physical Description: The handsome, well-proportioned skewed 52'-long single-span brick arch bridge has rusticated random-course ashlar spandrel walls finished with voussoirs and an inscribed keystone on the upstream side. It was widened with an approximately 20'-wide skewed reinforced concrete addition on the downstream side in 1922. The addition was also finished with a rusticated ashlar spandrel wall. Both sides have stone parapets capped with large rectangular blocks of rusticated granite. In the inside face of the downstream parapet is a stone tablet documenting the bridge committee. The intrados of the brick section of the span was gunited, but much of the coating has spalled off. The brick arch is separating from the stone spandrel wall.

Historical and Technological Significance: The large, impressive 1891 brick arch span, located just below an abandoned three-span stone arch bridge dating from 1824 and upstream from Speedwell Lake dam (rebuilt in 1938 as a W.P.A. project), ranks as one of the largest and most complete brick arch bridges in the state. The lake was once a power source for the Speedwell Iron Works, a major local industry owned by Stephen Vail, a prominent citizen and county judge. The bridge is an unrated resource located within the boundaries of the Speedwell Village Historic District that includes the lake, foundations of industrial structures, the extant Vail Mansion, and various out buildings (Criteria A, C).

The bridge was built in 1891 as part of the Speedwell grade improvement that eased the road grade at both ends of the bridge, a project that had been discussed by the Freeholders for nine years before the bridge contract was awarded. At the time of construction, the old bridge was still in service, but was subsequently damaged severely when the timber cribbing dam failed in a 1917 flood.

When the old road was incorporated into the state highway system, the 1891 bridge has been widened in 1922. The reinforced concrete extension was designed by the New Jersey State Highway Department Bridge Division, and it was finished to resemble the historic span. The historic alteration does not detract from the historical or technological significance of the original portion of the span, which is one of the largest brick arch bridges in the state.

The bridge is also important historically since it dates from the gilded age of Morristown, when wealthy New Yorkers vacationed in large mansions and the present commercial structures in town were built to accommodate the carriage trade. Included in this building boom are six large stone churches and the courthouse wall, also built by local stone masons.

Boundary Description and Justification: The bridge is located within a historic district that is listed in the National Register of Historic Places. Therefore, the span and its surroundings have been evaluated as eligible.

SETTING / CONTEXT The bridge is located in a wooded section of the township. A garden apartment complex is adjacent to the bridge on the east, while the remnants of a mill dam are to the west. Also on the west is a mid-19th century stone grist mill, converted to a gift shop, and a lawn adjacent to the brook. The bridge carries two lanes of traffic and shoulders over a minor stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed slab span is one of four similar bridges that accommodate the stream as it winds downhill to Flanders. The use of concrete for all structural parts of the bridge is typical of the period. The steel guiderail is the only alteration to the structure. However, there are no signs of previous rails or parapets. The structure is typical of short spans used in the state highway projects of the 1920s and is not significant technologically or historically.

SETTING / CONTEXT Located just below the concrete dam and spillway of Lake Musconetcong, the bridge is contiguous to a lake-front park on the Stanhope side. Both the bridge and dam were built by the state as part of the abandonment of the Morris Canal in the mid-1920s, when the canal was systematically dismantled after 100 years of service. The bridge carries two wide lanes of traffic and two sidewalks over a major watercourse. The area surrounding the lake is a public park.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Potentially eligible Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete T beam bridge is finished on a unornamented, utilitarian style. The steel picket fence along the spillway of the Lake Musconetcong dam replaced a waist-high solid concrete parapet early in the life of the structure. The original parapet remains on the downstream side. While the bridge is technologically undistinguished, it is historically significant as one of the major structures built as part of the ambitious Morris Canal abandonment directed by engineer C. Vermeule.

INFOR MATION

Bibliography:
Vermeule, C. Jr. Morris Canal and Banking Company Final Report of Consulting and Directing Engineer. 1929.
Morris County Engineer; Bridge File.

Physical Description: The reinforced concrete T-beam bridge is one element in a larger reinforced concrete dam and spillway at the bottom of Lake Musconetcong, which forms the boundary between Morris and Sussex Counties. The dam has a straight spillway to a concrete floor, where the water flows west and then south under the short bridge located below the brick-faced gatehouse with concrete quoins. The long spillway also serves as an overflow. The 4' paneled parapet of reinforced concrete on the south side of the bridge is original. The long steel picket fence along the spillway is a replacement for a similar concrete parapet early in the history of the dam and bridge, to enhance the view of the lake from the roadway.

Historical and Technological Significance: Located at the bottom of Lake Musconetcong, the bridge, dam, gatehouse, and surrounding park were part of the ambitious 1924-1928 Morris Canal abandonment project. The project, which closed and disposed of the former canal 88-mile long right-of-way and all the structures there unto pertaining, was designed and directed by Cornelius C. Vermeule, a consulting engineer from East Orange, New Jersey, who was hired by the Morris Canal and Banking Company Board of Directors. The "Morris Canal Abandonment Acts" passed by the New Jersey legislature in 1924 specified that the canal reservoirs, like Lake Musconetcong, would be dedicated to public use, but that they had to be fitted with dams and sluice gates. Vermeule designed the new water retention facility of reinforced concrete to ensure its permanence.

Lake Musconetcong was created as a reservoir for the Morris Canal, whereas other water sources were already existing bodies that were dammed higher to provide more water. The canal crossed the lake and entered a lock about 50' west of the current gatehouse. Over the active life of the canal (1824-1924), summer cottages were built around the lake shore. When the canal was abandoned, the State felt an obligation to retain property values along the lake front.

While the bridge is not technologically innovative, it is significant as a Morris Canal abandonment structure. Plaques on the gatehouse give brief details of the dam and history of the Morris Canal. It is one of two bridges built in Morris County as part of the canal abandonment project 1924-1928.

Boundary Description and Justification: The bridge is one part of a larger water retention facility that includes, but is not limited to, a gatehouse, dam, spillway, and surrounding park. The structure and surrounding park are historically significant because of they were developed as part of a historic and important regional improvement campaign. Therefore, the entire water retention facility and the body of water and its shore are evaluated as eligible.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS NJT HBS 03/12/91. SHPO Letter 6/30/95.

SUMMARY Built in 1928 by the Phoenix Bridge Co., the large, 4-span, open deck, steel deck girder bridge has ashlar abutments and massive concrete piers. A wood walkway is cantilevered from the north side. The bridge is not the first bridge at the site, the Gladstone Branch from Summit to Bernardsville was constructed by the West Line RR in the early 1870s. The bridge is not significant to the historical development of the railroad. It is historically and technologically undistinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT Located at the edge of the central business district, the bridge is adjacent to a one-story frame train station, which is stylistically older than the bridge. The structure carries two lanes of traffic and two sidewalks over two railroad tracks and a local road. The road is on the Morris Canal right-of-way, listed in the National Register. The bridge dates from 12 years after the abandonment of the canal and is not within the period of significance of the canal.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The six-span viaduct with a thru girder main span over the railroad and deck girder approach spans is supported on concrete abutments and columns. The paneled parapets are stylistically similar to the those used on other Boonton Line overpasses. The bridge is a representative example of its types and is neither technologically innovative nor historically significant. Thru and deck girders are commonly used in combination for viaducts and overpasses prior to 1945.

SETTING / CONTEXT The bridge is located at the end of the main business district. It is contiguous to an out-of-service 1904 station which is listed in the National Register, but the bridge is not included in the nomination. Built during the period of grade crossing elimination of the Boonton Line, the bridge replaced an earlier wooden span. It carries two lanes of traffic and two sidewalks over two active tracks.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The partially encased thru girder with floor beams bridge is supported on a concrete substructure and has concrete balustrades identical to those at 1464154 added in 1927 to the cantilevered sidewalks. Reproduction light standards have been added. A "steel bridge" is first identified at this crossing on the 1916 Sanborn map of Boonton, and the map is the source of the date. The bridge and its later balustrades are both representative examples of common types and are not noteworthy.

DESIGNER/PATENT UNKNOWN **BUILDER** WEST VA. BRIDGE & CONST.

SETTING / CONTEXT The bridge is located in a wooded section of a formerly industrial town of Boonton. To the south is a low-density residential area and to north, adjacent to the bridge, is an abandoned freight yard and the 1909 Delaware, Lackawanna & Western RR station, currently used as a warehouse. The bridge carries two lanes of traffic and two sidewalks over the abandoned railroad right-of-way that was the main line to Boonton until the DL&W changed the route about 1909.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Potentially eligible DL&W Boonton Line Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The stringer bridge with concrete jack arches replaced an earlier structure, for which the high rusticated stone abutments and wingwalls were built ca. 1875. The bridge is associated with the DL&W RR as it crosses what was until about 1909 the mainline into Boonton. It is individually technologically significant as an early and complete example of a corrugated metal lined concrete jack arch. The pipe railings with unusual cast iron posts with ball finials are well preserved. The bridge was part of the ca. 1905-1910 realignment of the DL&W route into Boonton.

INFOR MATION

Bibliography:
Darnell, Victor. Directory of American Bridge-Building Companies 1840-1900. 1984.
Morris County Freeholders Minutes. June 14, 1905; Dec. 13, 1905.

Physical Description: The 1905 40'-long steel stringer and concrete jack arch superstructure is supported on earlier high ashlar abutments. The jack arches retain the corrugated pattern of the metal forms used in their construction. Tie rods pass through the arches and stringers and are connected to the fascia stringers by nuts. Utility pipes are carried under two bays of the bridge. As well preserved as the underside of the span is the upper level with its original three rail pipe railing with cast posts finished with ball finials. The concrete deck has been covered by an bituminous concrete wearing surface.

Historical and Technological Significance: One of two steel stringer bridges with concrete jack arches identified in Morris County, the 1905 one that carries Morris Avenue over the Delaware Lackawanna & Western Railroad's spur to its Boonton freight station, ranks as the earliest example of its type in the county and one of the most complete in the region (Criterion C). Jack arches, placed between the stringers, were a bridge construction detail introduced in the 1880s in brick to assist with distribution of live load and formed an integral part of the bridge deck. By about 1905 concrete, with both a smooth or corrugated surface, was replacing brick, and by about 1914, the use of jack arches declined. Stringer bridges with jack arches from the 1885-1915 era are relatively common in northern New Jersey. What distinguishes this example as being technologically noteworthy is its date of construction and complete state of preservation. With its original pipe railings, which are also typical of the period, it is a well-preserved example of a bridge building technology that was common in the early decades of this century (Criterion C).

The bridge was built for Morris County by the West Virginia Bridge & Construction Company at a cost of $450.00 (Morris County Freeholders Minutes, 6/14/1905). The bridge building company was incorporated in Wheeling West Virginia in 1894, and it is believed to have been active until about 1906. There are several examples of the firm's work throughout New Jersey.

Boundary Description and Justification: Because the bridge stands on its own technological merits, it the span alone (superstructure and substructure) that is evaluated as eligible.

SETTING / CONTEXT The bridge carries 2 lanes of traffic and 2 sidewalks over 4 lanes of traffic on NJ 70. The overpass is at a busy intersection with gas stations, convenience stores, and hotels.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed 2-span encased steel stringer bridge has concrete balustrades, and concrete abutments and pier with Moderne detailing on the pilasters. Beam guide rails have been added, and chain link fences have been attached to the balustrades. In 1936 the bridge was built as a grade elimination project during the widening of NJ 70. The bridge is a representative example of a NJ State Highway Dept. bridge type, and is not historically or technologically distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** AMERICAN BRIDGE COMPANY

SETTING / CONTEXT The bridge carries two lanes of traffic and a sidewalk over Beaver Dam Creek near its confluence with the Metedeconk River. The surrounding area is heavily developed with marinas and modern residential structures. The swing span is operable, and is opened to navigation every half-hour during the busy summer boating season. The original operators' shanty is located at the southeast bridge approach.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 10/28/82

SUMMARY The bridge is a center-bearing thru girder and floorbeams swing span with 5 steel stringer approach spans. The operative moveable bridge is representative of swing span technology that was waning in the early 20th century. Earlier and better preserved examples survive (02000I1,1701399). In c.1955 the control panel was replaced, and in 1975 the original motor and open gear sets were replaced with modern equipment. The bridge is not historically or technologically distinguished.

INFOR MATION

SOURCES:
Ocean County Engineer, Bridge File.

PHYSICAL DESCRIPTION: The main span of the 7-span bridge is a built-up thru girder with floor beams center-bearing swing span of 62' in length. It is 20' wide and has a steel grid deck. The center pier is concrete. The moveable span is operated by an electric motor and enclosed reduction gears and sealed bevel gear that engages the rack and pinion drive. The present motor and sealed unites are 1975 replacements of the original motor and open gear sets.

The wood frame operators' shanty is located at the southeastern corner of the bridge. The span is open to navigation on a regular schedule during the summer months.

The five approach spans, 3 to the south and 2 to the north, are steel stringer spans. The substructure consists of timber pile bents. The bridge fenders are also timber piles. A timber sidewalk with chainlink fence is cantilevered off the bridge's eastern side.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE. The 1933 Beaver Dam Road Bridge is one of less than one dozen center-bearing swing span bridges identified as surviving in the southern half of the state. Center-bearing swing span bridges were a common moveable bridge type in the second half of the 19th century, but they were increasingly replaced by bascule bridges in the 20th century. Bascules held several advantages over swing spans including opening and closing more quickly, requiring less waterfront area, and providing wider and clearer channels. The 1933 Beaver Dam Road Bridge was probably one of the last highway swing span bridges constructed in the state. It was not technologically innovative and was representative of earlier center bearing swing span construction. Older and more historically significant examples of center-bearing swing span technology exist including the 1896 Union Avenue over Passaic River (02000I1, Bergen County, Rutherford Borough), the 1904 Port Republic Road over Nacote Creek (01PR007, Atlantic County, Port Republic City), the 1905 New Bridge over Alloways Creek (1701399, Salem County, Lower Alloways Township), the 1908 Court Street over Hackensack River (020004A, Bergen County, Hackensack City), and the 1920 Main Street over Delaware and Raritan Canal (3000168, Somerset County, South Bound Brook Borough).

The Beaver Dam Road Bridge was built for the county by the American Bridge Company, which was formed in 1900 as a conglomerate of smaller fabricators. After its formation, American Bridge Company was responsible for over 50% of the bridge building capacity in the nation. The bridge retains its original superstructure, drive pinion and rack, and operators' shanty. The present control panel and lock mechanism dates to ca. 1955, and the sealed units and electric motor date to 1975. The original timber stringers in the approach spans were replaced with rolled steel I-section stringers ca. 1989, but the substructure remains timber.

 # SPANS 41 **LENGTH** 1120 ft **WIDTH** 28 ft

CONSTRUCTION DT 1938 **ALTERATION DT** 1975 **SOURCE** PLAQUE

DESIGNER/PATENT ASH, HOWARD, NEEDLES & TAMMEN **BUILDER** EASTERN ENGINEERING CO

SETTING / CONTEXT The two-lane bridge with sidewalk spans the northern tip of picturesque Barnegat Bay between Mantoloking Neck on the mainland, and Mantoloking Borough on Island Beach. Mantaloking Borough has many well-preserved early-20th century cedar-shingled bungalows next to and south of the bridge. On the mainland side of the bridge are numerous marinas. The bridge's two main spans cross the Intercoastal Waterway.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The main span of the 41-span bridge is a single leaf trunnion bascule haunched deck girder with floor beams. It is matched by a fixed haunched deck girder on the west approach, and the other approach spans are T-beams on timber pile bents. The operating mechanism with open gear sets and enclosed differential are original but worn. The bridge, one of the best examples of its type in the region, is historically and technologically significant.

INFOR MATION

SOURCES:
Brick Township Historical Society. Brick Township Changing Scenes. Brick Township, NJ: 1980.
Ocean County Engineer. Plans and Files. 1938.
Perkons, George. AGLAS. Personal File: Mantoloking Bridge.

PHYSICAL DESCRIPTION: The 1120'-long bridge over Barnegat Bay is composed of a single leaf trunnion bascule haunched deck girder main span, a matching haunched deck girder to the west, and 39 concrete T-beam approach spans, 15 to the west and 24 to the east. The T-beam spans are supported on timber pile bents and have concrete post-and-rail railings. The moveable span is 58' toe-to-trunnion, and is 28' wide with an open steel grate deck. The cantilevered sidewalk with a modern metal railing is on the south side. Modern crash gates have been installed and the fender system is timber.

The operating controls and drive mechanism are housed in a three-story hexagonal-shaped concrete tenders' house with a standing seam metal roof and double hung windows. The operating mechanism appears to be relatively unaltered. The original trolley-like controls were replaced with a modern panel in 1975, but the gearing, with an enclosed primary reducer and open gear sets for the secondary reducer and drive gear, is original as are the trunnions and built-up trunnion tower. The gears are worn, and the rack and pinion are thin. The concrete counterweight is fixed to the tail end of the moveable leaf.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Mantoloking Bascule Bridge is a historically and technologically distinguished as one of the most complete examples of the Ash, Howard, Needles & Tammen moveable bridge design that is common in the region. It is eligible under National Register Criterion C. With the expiration of the Strauss patents in the 1920s, other designs gained currency, especially the Ash, Howard, Needles & Tammen trunnion bridge with a counterweight fixed to the tail end and a span support that incorporated patented details (U.S. Patent No. 1633565, 1927). The technology used in the design, which is well represented in southern New Jersey where over 10 similar spans were built in the 1930s and early 1940s, is not innovative as the trunnion bridge was perfected in the 1910s. The Mantoloking Span is notable because, with the exception of the control panel and c.1955 steel grid deck on the moveable span, it is well-preserved and unaltered. It is more complete than other examples (i.e. 1511150, NJ 70 over Manasquan River, Point Pleasant Borough).

In 1938 the bridge was constructed to replace a 7-panel Warren truss swing span, probably built c.1915. The 1938 bascule was designed by the engineering firm of Ash, Howard, Needles, and Tammen, consulting engineers based in Kansas City. State Highway Engineer, Morris Goodkind, also acted as a consultant on the project. Eastern Engineering Corporation contracted to build the bridge and was paid in part by federal Depression-era work relief program funds, a common arrangement for 1930s bridges in the state.

BOUNDARY DESCRIPTION AND JUSTIFICATION: The bridge is individually eligible, in and of itself, including superstructure, substructure, operators' buildings, and right-of-way over the river.

New Jersey Department of Transportation. Bridge Plans. 1936, 1991.

PHYSICAL DESCRIPTION: The 625'-long bridge over the Manasquan River is composed of a single leaf trunnion bascule haunched deck girder main span, a matching haunched girder to the north, and 16 other T-beam approach spans supported on concrete pile bents and finished with concrete post-and-rail railings. The movable span is 56' toe-to-trunnion with a concrete counterweight attached to the tail end, steel grid deck and pipe railings. Modern beam guide rails and crash gates have been installed. The fender system is timber.

In 1991 the bascule operators' houses and operating mechanism were rehabilitated. Improvements included computerized operators' controls, installation of sealed unit speed reducer gears, modern motors and brakes, and automated gate systems. The two-story operators' houses received new metal roofs, windows, doors, and exterior stucco.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The NJ 70 over Manasquan River bridge (1936) is one of over ten similar 1930s Ash-Howard-Needles and Tammen bascule spans in southern New Jersey. The NJ 70 span is one of the least well-preserved examples of the bridge type because of significant alterations to the operators' houses and operating mechanism. Other bridges, such as 1506006 (Mantoloking Road over Barnegat Bay, Brick Township, 1938) and 1300S31 (CR 8A over Navesink River, Monmouth County, Middletown Township, 1939), are more complete and thus better representative examples of the historically important movable bridge technology. The Ash-Howard-Needles and Tammen trunnion bascule design became popular in the late-1920s after the expiration of the Strauss bascule patents.

The NJ 70 bridge was constructed under the administration of the NJ State Highway Department and was funded in part by federal work-relief money, a common arrangement for 1930s bridges in the state. The original route designation of the bridge was NJ 34.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The 4-lane bridge with median, shoulders and sidewalk spans a small creek about 1/4-mile west of the intersection of NJ 72 and the Garden State Parkway. The area is moderately developed, and a business park (c.1980) is located just south of the bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1930 skewed, single-span, encased steel stringer bridge with a concrete balustrade was widened in 1968 with prestressed concrete beams with parapet on the upstream side. The addition was built to accommodate the expansion of NJ 72 into a divided 4-lane highway. The 1930 bridge was originally built as part of NJ Route S40, later redesignated NJ 72. It is a common NJ State Highway Department bridge type, and is not historically or technologically distinguished.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The thru truss rim-bearing swing span bridge on an ashlar substructure was erected in 1906 by the Owego Bridge Co. It is of riveted construction with the exception of the center tower, which has pinned top chords composed of stamped eye bars. The bridge has been altered. In 1985 the operating machinery and operator's house located above the roadway were removed. The flooring system was replaced, and additional section was bolted onto some verticals and diagonals. However, the changes do not preclude the individual eligibility of this structure for listing in the National Register of Historic Places under Criterion C as a representative example of a through truss rim-bearing span. All of the key visual elements of the bridge - the trusses by the Owego Bridge Company, the center pier, the wheels that run on a track making it a rim - bearing span, and the ashlar abutments retain integrity.

SETTING / CONTEXT The bridge carries a 2-lane road, 2 sidewalks, and a utility pipe over the Passaic River on the boundary between Passaic and Bergen counties in an industrial section of Passaic. It is one of 3 moveable spans in Passaic.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Finding 11/23/94, Letter 6/30/95.

SUMMARY The main span of the 3-span riveted Warren pony truss bridge is an 86' Strauss overhead articulated counterweight bascule span. It is supported on a concrete substructure. While the superstructure is complete, the operating controls and equipment was removed ca. 1977. The operator's house was removed after that. The gearing remains. Although altered, the span retains enough of its original fabric to maintain its technological significance as a rare example of an important moveable type.

INFORMATION

Bibliography:
Passaic County Engineers Office. Bridge File: 4.
Waddell, J.A.L. Bridge Engineering. 1925.

Physical Description: The main span of the 229'-long riveted Warren pony truss bridge is 85'-long is a Strauss articulated overhead counterweight single leaf bascule span. The entire bridge is supported on a concrete substructure. The lift span is a rivet-connected Warren pony truss span with a 32' roadway. It is traditionally composed of built-up members as are the trunnion columns, braced counterweight tower, and counterweight linkages that permit the counterweight to pivot and move parallel to itself during operation of the bridge. The steel grid deck was installed in 1965 as part of an upgrading of the floor system. The most significant alteration to the bridge has been the demolition of the operators shanty and operating controls for the electric-motor powered span some time between 1976 and 1979. The bridge has been fixed in the closed position, but the gear sets and shafts are still in place as is the chain-operated manual operation. Plans for the original mechanical systems is preserved in the County Engineers office. The original metal sidewalk railings are still place.

Historical and Technological Significance: The 1915 Strauss overhead articulated counterweight bascule bridge designed by the Strauss Bascule and Concrete Bridge Company of Chicago, Illinois, is one of the few examples of the technologically important bridge type remaining in the state. Despite the fact that it was once the most popular moveable bridge type in the country in the early 20th century, about six built between 1907 and 1938 remain in the entire state. Because of the diminishing number, each example that retains the technologically innovative patented articulated counterweight detail are considered as technologically and historically important.

J. B. Strauss (1870-1938) invented the pivoting counterweight linkage used at the Eighth Street bridge, and he applied for a patent in 1905, the same year the first bridge of this type was built in Cleveland. That year he also founded the Strauss Bascule and Concrete Bridge Company in Chicago to market his bridge designs. Strauss went on to become the most widely respected moveable-span bridge engineer of the pre-World War II era.

Strauss reasoned that if, unlike the traditional trunnion bridge, which operates like a seesaw and moves in a vertical plane on a horizontal steel pivot, the entire weight of the counterweight could be concentrated at the end (tail) of the moveable leaf, it would then be possible to use a lighter counterweight. Such an arrangement also meant a shorter tail end to the leaf, thus saving on materials that the "counterweight could be made in such shape that no pit is required to receive it when the leaf is in the upright position'" (Waddell, p. 704). The patented linkage, or arms, ensures that the counterweight will always move in a series of parallel positions and thus maintain the position of the weight at the tail end of the leaf.

This example is altered, but not to the degree that the technologically significant elements have been lost. The span was fixed about 1976, and the operators house and controls were removed by 1979. Despite the loss of the operator's house, the superstructure survives in a remarkably complete state of preservation making this bridge one of the most important of its type in New Jersey. Much of the gearing and the counterweight linkage survive as does the uncommon chain-driven manual operation. A machinery plan for the bridge survives, so how the operating mechanism was arranged is well documented.

Boundary Description and Justification: The bridge is evaluated as significant on its own merits. The surroundings do not contribute to the significance of the span, so the boundary is the limits of the span itself. This includes the structure and the superstructure.

SETTING / CONTEXT The bridge carries two lanes over the Passaic River at the boundary between Bergen and Passaic counties at a T intersection. The Passaic County side is adjacent to a late-19th century industrial plant now used for chemical production while the Bergen County side is dominated by early-20th century detached homes in the suburban community of Fair Lawn.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span pin-connected Pratt thru truss bridge supported on concrete abutments and a cutwater pier is a well-preserved example of its type. Aside from impact damage and the 1925 and mid-1960s replacement of the sidewalk brackets and stringers, the span is largely unaltered. The original lattice railings survive. The undocumented bridge was built after the disastrous 1903 flood that claimed most of the bridges in the Paterson area. It is one of 3 significant thru truss bridges in the county.

INFOR MATION

Bibliography:
Passaic County Engineer. Bridge File, 9.
Minutes Passaic County Board of Chosen Freeholders. 1903-1905.
"Flood Damage to Bridges at Paterson, N.J. Engineering News. Vol. L, No. 18 (October 29, 1903), pp. 377-378.

Physical Description: The skewed 2-span pin-connected and riveted Pratt thru truss bridge with a cantilevered sidewalk on the downstream side is supported on concrete abutments with wingwalls and a center cutwater pier. The top chords and inclined end posts are built-up box members with lacing on the underside. The verticals are laced toe-out channels, and the diagonals and bottom chords are stamped eye bars. The span marks the transition from pinned to riveted field connections. The upper panel points are pinned while the lower panel points have pins for the bottom chords and rivets for connecting the floor beams to the verticals. The floor beams are built up and set on the skew. The lattice portal brace has been strengthened by the addition of plate corner braces welded in place in the mid 1960s. One of the most significant features of the bridge is the survival of the handsome lattice railings set inside the truss lines. The railings are accented with rosette bosses. The deck is a modern steel grid deck placed in the mid 1960s.

Historical and Technological Significance: The well-preserved 2-span pin-connected and riveted Pratt thru truss bridge built in 1905 to replace a span lost in the October, 1903 flood, ranks as the only example of its type in the county. It is also significant in that it marks the transition from pinned to riveted field connections. Its location in an urban area makes its a remarkable survivor form an era when load and traffic needs were much different. Despite some impact damage, the bridge remains in service on a busy intercounty road appearing and functioning much as it did in 1905 when it was completed. It survives as a good representative example of its truss type and fabrication technology (criterion C).

The bridge is one of four thru truss spans in the county, and it is the only one that has pin connections. It is a late example of a pin-connected bridge. By 1905 most metal thru truss bridges had riveted field connections. No original plans survive, and the fabricator is not documented in the county engineer's records. The bridge is one of many in Passaic County that were built after the 1903 flood that carried away ten bridges on the section of the Passaic River between the Great Falls in Paterson and Dundee dam in Clifton, about two miles downstream from the falls.

Boundary Description and Justification The bridge is individually significant. No significant cultural resources are contiguous to the bridge. Therefore, the boundary is limited to the substructure and superstructure of the span itself.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1907 3-span elliptical reinforced concrete deck arch bridge is a large example of its type, but it is not early nor is it well preserved. Significant detailing has been lost through deterioration and impact damage. What remained of the pipe railings with cylindrical cast iron posts was removed in 1993. Large sections of the stepped cap have been lost. The span was rehabed in 1993. More complete deck arch bridges survive in Paterson (1600390). This one is too altered to be noteworthy.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The heavy rivet-connected 6-panel Pennsylvania thru truss bridge with cantilevered sidewalks is supported on ashlar abutments from a previous span lost in the 1903 flood. In addition to being a rare example of the truss type applied to vehicular use, the 1907 bridge is well preserved with alterations apparently limited to the flooring system. The bridge is technologically significant because of its type and state of preservation.

INFOR MATION

Bibliography:
Passaic County Engineer. Bridge File 14.
Condit, Carl. American Building Art The 19th & 20th Century. New York, 1960.
Minutes. Passaic County Board of Chosen Freeholders. October 15, 1903.

Physical Description: The 6-panel Pennsylvania thru truss bridge of riveted construction is supported on brownstone ashlar abutments from a previous superstructure. The span is 255' long and 30.7' wide, and it survives in virtually unaltered condition. It is composed of traditionally built-up box members for the top and bottom chords and inclined end posts while the diagonals, verticals and sub ties and sub struts of the center subdivided panels are either laced channels or angles. While displaying no unusual construction details, the span is a good representative example of its type. The cantilevered sidewalks are enclosed by lattice-pattern railings that extend beyond the superstructure and also enclose the approaches.

Historical and Technological Significance: The 1907 riveted Pennsylvania thru truss bridge is historically and technologically significant as a well-preserved example of an uncommon truss type (criterion C). The Pennsylvania truss, a Parker variation on the Pratt truss with sub ties (tension) and sub diagonals (compression), or subdivided panels, was devised by Albert Fink in the late 1860s for the Pennsylvania Railroad's bridge across the Ohio River at Louisville. The engineers at the Pennsylvania Railroad immediately saw the merit of Fink's design, and they worked to simplify his design by reducing the number of intermediate members in each subdivided panel. By 1875, Fink's design had been developed in the Pennsylvania, or Petit, truss type represented by the Straight Street bridge. The polygonal top chord allowed for strength in the trusses where they are most needed balanced with economy of material, and it became a standard detail for long-span metal truss bridges after about 1875. The addition of a subdivision to center panels of Pratt trusses grew out of a recognition of the stress reversal from live loads through the length of the trusses. The Straight Street bridge is one of the few Pennsylvania truss highway bridges in the state. The truss type is more commonly associated with railroads.

The earlier span at this crossing was lost in the October, 1903 flood that carried away most of the bridges in the center of Paterson. A temporary wooden bridge was built at the crossing. The Pennsylvania thru truss replacement, not completed until 1907, was designed by then county engineer Colin R. Wise. Because of its location in what was then an industrial area of Paterson, the bridge was designed for heavy live load capacity. The bridge type is thus reflective of the historical development and use of the surrounding area. Unfortunately, much of the historic context of the span has been lost through modern urban renewal program redevelopment.

Boundary Description and Justification: The historic context of the bridge has been lost due to demolition of some of the historic factories and housing that surrounded it. The area does not have historic district potential. The bridge is evaluated as individually significant, and the boundaries are limited to the span itself, the superstructure and the substructure including the wingwalls.

SETTING / CONTEXT The bridge originally carried two lanes of traffic and two sidewalks over the Passaic River, but the roadway has been closed to vehicular traffic. It, like the other bridges in Paterson, serves as a link between the late-19th and early-20th century residential districts on the west side of the river from the industrial east side. The bridge contributes to the historic character of the area.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 5/26/89, Letter 6/30/95.

SUMMARY The 11-panel pin-connected Parker thru truss bridge supported on coursed ashlar abutments is a large and well preserved example of the truss type that is not common. Parker trusses are more commonly found on rail lines rather than city streets. The span is technologically distinguished because of its type, a polygonal top chord variation of a Pratt truss, and its state of preservation. It is also historically notable as one of the significant Paterson bridges built after the 1903 flood.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-preserved metal 3-span 3-hinge arch bridge built in 1900 is supported on an ashlar substructure. It ranks as one of the technologically most significant spans in the region. Designed and fabricated by F.W. Long (1856-1911), a noted local contractor who formerly worked for Dean & Westbrook of NYC as their agent in Bergen & Passaic counties. The plaque identifies him as the designer of this unique and early example of the bridge type which is also significant for its fine detailing.

INFORMATION

Bibliography:
The Evening Record (Hackensack, N.J.), August 30, 1911.
Condit, Carl. American Building Art 19th Century. New York, 1960.

Physical Description: The handsome 3-span, 231'-long, ribbed three-hinge steel arch bridge with braced spandrels is supported on ashlar abutments and cutwater piers. Each elliptically shaped arch is composed of 5 arch ribs. The spandrel braces on the fascia arches are detailed in the classical taste as an arcade with the column-like verticals set on richly molded cast bases, and the arch spandrel is filled with a quatrefoil pierced panel. The hinges are located at each skewback and at the crown of each rib. The arch ribs are composed of built up members of angles and web plate. The cantilevered sidewalks on each side of the well-proportioned span are enclosed by metal railings that date to 1915. The originals were lost in the 1903 flood. The bridge appears to be unaltered.

Historical and Technological Significance: The three-hinge ribbed arch bridge built over the Passaic River at Paterson in 1900 ranks as the most distinguished example of the uncommon bridge type in the state (criterion C). In addition to its technological significance, the well-preserved span designed and fabricated by the F.R. Long Company of Hackensack is one of the most architectonic spans in the region. The detailing and workmanship of the castings is unmatched in the period.

The three-hinge metal arch was introduced into this country by Philadelphia engineer John M. Wilson, an engineer with the Pennsylvania Railroad, in 1869. It had been used in Europe about 20 years prior to its American appearance, and it was preferred over hingeless arches because of its ability to accommodate strains from expansion, contraction, and settlement. Few three-hinge arch bridges were built in the 1870s, but in the 1880s and 1890s, several significant examples, like the 1892 Strawberry Mansion span in Fairmont Park in Philadelphia and the 1896-1897 Panther Hollow Bridge in Pittsburgh were erected. While not an early nor a long or dramatically sited example of its type, the Main Street Bridge in Paterson ranks as one of the most handsome and richly detailed bridges of the turn-of-the-century era in northern New Jersey. The architectonic castings for the classically detailed spandrel columns on the fascia arches are of particular note.

The bridge is the product of the F.R. Long Company of New York. Frank R. Long (1856-1911) was born in Philadelphia. He was an apprentice at the William Sellers & Company iron foundry in Philadelphia, and then secured a position with the Pottstown Iron Company. In 1889 he went to New York City to join the nationally prominent bridge fabricating firm of Dean & Westbrook (founded in 1884). He served as their agent in Bergen & Passaic counties until 1896 when he left to go into business for himself. In 1898 he formed the F.R. Long Company with a yard in Hackensack (Bergen County). The company built bridges in northern New Jersey. In 1908 he was appointed to the New York & New Jersey Interstate Bridge Commission for one term. In addition to his professional activities, Long was active in civic and social affairs in Hackensack. He left no children.

Long is representative of the age of the entrepreneur/bridge designer who, in the era before the consulting engineer or the professional county engineer, designed as well as built the bridge to meet the construction specifications defined by the county boards of freeholders. No original plans for the bridge were located in the county engineer's files.

Boundary Description and Justification: Alterations and demolitions have drastically altered the historic setting of the bridge. The bridge is evaluated as individually distinguished, so the boundary is limited to the span itself.

SUMMARY When built in 1897, the well-proportioned 3-span elliptical deck arch bridge with a patented Melan reinforcing system encased in concrete was not only one of the longest built by noted engineer Edwin Thacher, the American licensee of Melan's innovative designs, but it ranks as one of the earliest. The span, with its ashlar spandrel walls, is one of the most technologically significant steel and concrete bridges in the state based on its designer, type, date, and state of preservation.

INFORMATION

Bibliography:
"Three-Span Melan Arch Bridge Across the Passaic River, Paterson, NJ." Engineering News. March 16, 1899, p. 175.
"Flood Damage To Bridges at Paterson, N.J." Engineering News. Vol. L, No. 18 (October 29, 1903), pp. 377-378.
Jackson, Donald. Great American Bridges and Dams. The Preservation Press, 1988.

Physical Description: The handsome, well-proportioned 233'-long, 3-span, Melan steel and concrete elliptical arch bridge has coursed brownstone ashlar-faced spandrel walls and cutwater piers. They are backed by concrete. It is 54'-wide and carries a 2-lane city street flanked by wide sidewalks enclosed by metal railings with lattice panels on the bottom. The railings were installed in 1937 replacing the original. Each of the cinder-filled arch spans is approximately 89' long, and the rise is 9.5'. The bridge is built on the Melan system with 10" I-beams set 3' on center and embedded in concrete that varies in thickness from 15" at the crown to 66" at the skewbacks. Expansion joints are built in the spandrel walls over the piers to provide for thermal changes. The southernmost two spans were damaged in the 1903 flood and were repaired in kind at that time. The bridge is well preserved.

Historical and Technological Significance: When completed in 1898, the handsome elliptical arch bridge was the second longest Melan-type bridge in the country, ranking after a similar span in Topeka, Kansas completed in 1896-97. Industrial Historian Donald C. Jackson states that the Topeka bridge, completed about one year before the similar arch at Paterson, was the "first major reinforced concrete arch bridge in the United States" (p. 35). Thacher's bridge at Paterson is one of the most important concrete-steel spans in the Northeast based on its date, structural type, and remarkably complete state of preservation (criterion C). It is a nationally significant example of the Melan arch bridge technology, and it was designed by noted civil engineer Edwin Thacher. Thacher was a proponent of the Melan arch which is a series of parallel iron or steel I-beams curved to the profile of the soffit and encased in plain concrete. Joseph Melan, a Viennese engineer, was granted an American patent for his design in 1894. Fritz von Emperger, a German-born engineer, built the first Melan arch in the United States at Rock Rapids, Iowa, and he is credited with popularizing the design in this country. Emperger made additions to the Melan system, adding a beam to the deck and joining the deck and arch beams by means of bars set on radial lines. He was granted a patent in 1897 for the changes to Melan's patent.

Edwin Thacher and William Mueser formed the Concrete-Steel Engineering Company in New York City in 1901, and the firm was responsible for many important Melan-type bridges in the country, including the 8-span Grand Avenue Viaduct, Milwaukee, Wisconsin, built in 1907; a 7-span Melan arch built at Wichita, Kansas, built in 1911; the 6-span Hudson River bridge at Glens Falls, New York, built in 1914-15; the bridge over the Mississippi River at Minneapolis composed of five 231' spans built in 1907. Thacher was a versatile engineer who received many patents including one for the "Thacher Cylindrical Slide-Rule," the "Thacher Steel Bridge Truss," the "System of Concrete Steel Arches," and the "Thacher Combination Bridge Truss" among others. He held positions of chief engineer for the Decatur Bridge Company of Decatur, Alabama, and the Keystone Bridge Company of Pittsburgh before opening his own consulting firm in Louisville, Kentucky. He was responsible for the 1891 Walnut Street bridge across the Mississippi River at Chattanooga and the 1892 Costilla Crossing bridge over the Rio Grande in Colorado which was an example of the Thacher truss patented in 1884 and designed to reduce the effect of temperature stresses on truss members. Thacher formed a partnership with W.H. Keepers in 1894 at Detroit, and the partnership lasted as Thacher and Keepers until October of 1899. It was this firm that designed the West Broadway bridge at Paterson. Thacher remained with the Concrete-Steel Engineering Company until his retirement in 1912. The Melan arch was replaced in popularity in this country by the reinforced concrete arch span.

The Thacher & Keepers-designed Melan-type arch bridge is one of two in the state designed by Edwin Thacher. The other is located in Branch Brook Park in Newark (Essex County) (0700101). It was designed by the Concrete-Steel Engineering Company in 1905. Both are technologically and historically important as examples of the experimentation associated with the introduction of concrete and steel arch bridges in this country.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The area around it has been redeveloped and has lost most of its historic character. Consequently, the historic setting for the technologically distinguished span has been lost. The boundary is limited to the span itself.

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 9-panel riveted Pratt deck truss bridge erected in 1890 by the Passaic Rolling Mills is remarkably well preserved. Supported on high ashlar abutments and located next to a historic Beattie Carpet mill complex dating to 1848, the span ranks as one of the most distinguished examples of its type in the state. The roadway was widened in 1966 by incorporating the downstream sidewalk. The bridge is technologically and historically significant.

INFOR MATION

Bibliography:
Passaic County Engineer. Bridge File: 22.
Schriner, Charles. Paterson, Illustrated. Paterson, NJ: The Press Printing & Publishing Company, 1890.
Darnell, Victor. Directory of American Bridge Builders. 1984.

Physical Description: The one span, 132'-long rivet-connected Pratt deck truss bridge over the Passaic River below Little Falls is supported on high ashlar abutments. The bridge is made up of nine panels, and although there has been some strengthening of the original members, the trusses still perform as originally designed. The upper chords and verticals are toe-out channel with lacing and the diagonals are angles set back-to-back. The lateral and sway bracing are also composed of angle section as are the bottom chords. In 1966 one of the sidewalks was incorporated into the widened roadway. New floor beams and stringers were placed at that time. The original lattice railing was lost on the widened side, but it is in place on the cantilevered sidewalk on the other side. In 1975 welded strengthening was added to some truss members. The abutments have been sensitively rebuilt.

Historical and Technological Significance: The riveted deck truss bridge built in 1890 ranks as one the earliest and most complete examples of its type in the state (criterion C). It is also an early example of riveted field connections. Only two deck truss bridges from the 19th century were identified during the 1991-1993 New Jersey Historic Bridge Survey. The other example (1400084) is pin connected. The fabricator, the Passaic Rolling Mill of Paterson, is one of the important late-19th century iron manufactures and rolling mills in the country, but few bridges New Jersey bridges have been documented as their work. In addition to its individual technological and historical significance, the bridge is adjacent to the well-preserved Beattie Carpet Mill complex that dates to 1846. It was originally water powered and was in operation until the 1970s. The complex was determined eligible in SHPO finding in 1979.

The Passaic Rolling Mill at Paterson was chartered in 1869. In 1873 the company began rolling iron I beams and channel section. Many of the beams were used in building the country's early "skyscrapers" and the New York state capitol building at Albany. The company recognized the application of their products to bridge building, and they erected metal truss bridges for counties and railroads, especially the local Erie Railroad and the Delaware Lackawanna & Western Railroad. They also supplied iron for the New York City elevated street railways. By 1890 their bridge division had grown enormously, and bridges were being shipped to every state in the union and Central and South America.

Passaic Rolling Mill began producing steel in 1889. In 1890 the company employed about 1,000 persons, and in 1903 its output was 60,000 long tons. Steel became a more significant product, and by 1903, the company changed its name to the Passaic Steel Company. Later in the 1910s it was changed again to the Passaic Structural Steel Company. The yard was located on Straight Street at the Erie Railroad tracks. Despite the size of the and longevity of the mill, few bridges have been identified as their work. Some of their iron and steel sections and beams have been identified in other fabricator's bridges.

Boundary Description and Justification: The bridge is adjacent to a mill complex that has been determined to meet National Register criteria. The bridge was built within the period of significance of that mill complex, but it is significant independent of any association with the mill complex. The bridge is significant on its own merits, but its setting appears to be composed of contiguous significant resources.

SETTING / CONTEXT The bridge carries a 2-lane road and sidewalks over a river in a mixed-use area at the boundary of Morris and Passaic Counties. Structures adjacent to the bridge include a well-preserved 19th-century home, a tract of 1950s capes, and modern commercial buildings. The road, the Paterson-Hamburg Turnpike, was incorporated in 1806, and it remains a major link from the rural northern part of the county to the county seat at Paterson.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span encased stringer bridge is typical of the pre-World War II bridges with concrete used for the substructure, deck, sidewalks, and balustrades. A 1971 flood cracked and tilted the center pier and scoured part of the foundation of the west abutment. A reinforced concrete hammerhead pier was installed in 1972 to replace the original pier. The bridge is a representative example of a common bridge type and style and is not historically or technologically distinguished.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-span riveted Pratt pony truss bridge is made up of trusses 8 panels in length. It is supported on an ashlar abutments and piers and has cantilevered sidewalks. The chords are built-up members, and the diagonals are angles with battens. The most unusual detail of the well-preserved span are the verticals with web plate knee braces. The floor beams are also built-up. The lattice railings are original. Original plans do not survive. The span is significant for its design, size, & condition.

INFOR MATION

Bibliography:
Passaic County Engineer: Bridge File 39.

Physical Description: The 4-span, 8-panels each, riveted Pratt pony truss bridge is supported on brownstone ashlar abutments and piers. The top chord and inclined end posts are built-up members with angles, top cover plate and web plate. The verticals and diagonals fit inside the top chord with plate reinforcing for the rivets at the panel points. The verticals are angles with the triangular-shaped braces of plate at the inside face. Diagonals are composed of toe-down angles joined by battens. Some of the original built-up floor beams have been replaced by rolled section, wide flange beams. The sidewalks are cantilevered on brackets and enclosed by the original lattice-pattern railings with bolted outrigger braces. There are minor welded and bolted repairs to small sections of the trusses, and some verticals have been replaced by rolled section. On the whole, the bridge, now fitted with a steel grid deck and new stringers, is well preserved.

Historical and Technological Significance: The 4-span rivet-connected Pratt pony truss bridge built over the Passaic River in 1898 is technologically significant as the only example of its type in the county or the region (criterion C). That significance is enhanced by the fact that it is a multi-span bridge. It is well preserved, and it is one of the few truss bridges in the county to predate the 1903 flood. No plans for the span survive in the county engineers records, so the designer and fabricator are undocumented. The Pratt truss in the pin-connected version emerged as the most common late-19th century truss bridge type, but riveted Pratt pony truss bridges are not frequent. An unusual construction detail is the plate knee braces that are an integral part of the verticals. They add lateral stability to the truss lines. The span also retains its early sidewalk railings which add to its technological and historical significance.

Boundary Description and Justification: Because the bridge is evaluated as individually distinguished, the boundary is limited to the span itself, superstructure and substructure, including the abutments and wingwalls.

DESIGNER/PATENT GARWOOD FERGUSON, CO. ENGINEER **BUILDER** DANSEN CONSTRUCTION CO.

SETTING / CONTEXT The bridge is located just below the mid-1920s Raymond Dam of the Wanaque Reservoir. It was built for a realignment of Ringwood Avenue to accommodate construction of the reservoir complex which was executed in granite. The stone serves as a stylistic motif visually unifying the reservoir complex. The bridge carries two lanes of traffic and two sidewalks over the river just below the spillway. The bridge is not part of the reservoir complex.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Historic District Status Unresolved.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span encased stringer bridge is a representative example of a common type and design. The use of concrete for the substructure, sidewalks, and balustrades is typical the era. The span is not connected with the Wanaque Reservoir. Built on a realignment mandated by the reservoir project, it was built by the county (reservoir was not), and it is of a different finish material than the reservoir. The delineation between the two is clear. It is an undistinguished, independent structure.

 # SPANS 1 **LENGTH** 40 ft **WIDTH** 30.2 ft

CONSTRUCTION DT 1892 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT D. DEMAREST, ARCHITECT **BUILDER** ADRIAN WENTINK

SETTING / CONTEXT The bridge carries a 2-lane city street and two sidewalks over a brook in an urban area of Passaic with late-19th century brick industrial buildings and county buildings. The bridge is just north and in full view of the elevated, limited access NJ 21. Utility pipes pass through the intrados of the arch. A chain-link pedestrian fence has been added atop the parapets. The setting does not have historic district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-proportioned 40'-long brick arch span has rusticated-finish coursed ashlar spandrel walls, and the arch ring is accented with ringstones. Some sections of the south parapet are missing. The parapets are capped with bluestone. The handsome bridge is the most complete example of the three in the county, and as such it is technologically distinguished. Brick arches were commonly used in north Jersey in 1874-1905.

INFOR MATION

Bibliography:
Paterson City Directory. 1890-1896.
Pape, William. History of Passaic. 1899.

Physical Description: The handsome, well-proportioned 40'-long brick arch bridge with rusticated ashlar spandrel walls is finished with rusticated ashlar voussoirs in an alternating header and stretcher pattern. The parapets are topped with blue stone cap stones. A plaque is set in the north parapet. Utility pipes have been added. Some of the south side parapet is missing. A chain-link fence pedestrian barrier has been added atop the cap stones.

Historical and Technological Significance: The well-proportioned brick arch bridge is a handsome and documented example of its type. The brick arch was used in northern New Jersey from approximately 1870 through the 1890s, but few examples are as complete as this one. An earlier brick arch span built in Haledon in 1875 (1600124) was altered in 1924 when it was widened with a stringer addition. The other brick arch span in Passaic County in Clifton over the Third River (1600081) was also widened, and it has lost its integrity of original design from deterioration. The span is thus technologically significant as a well-preserved example of the type that was important in the evolution of bridge building in northern New Jersey (criterion C). No information was located on D. Demarest who is identified on the plaque as the "architect" of the bridge. It is known that he did not practice in Paterson. No original plans for the bridge survive.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is thus limited to the span itself.

STRUCTURE # 1600060 **CO** PASSAIC **OWNER** COUNTY **MILEPOINT** 0.0

NAME & FEATURE INTERSECTED LEXINGTON AVENUE OVER WEASEL BROOK **FACILITY** LEXINGTON AVENUE

TOWNSHIP CLIFTON CITY

TYPE STRINGER **DESIGN** ENCASED **MATERIAL** Steel

 # SPANS 1 **LENGTH** 30 ft **WIDTH** 40 ft

CONSTRUCTION DT 1903 **ALTERATION DT** 1949 **SOURCE** COUNTY RECORDS

DESIGNER/PATENT WILLIAM WHITMORE, CO. ENGINEER **BUILDER** HERBERT SANDFORD

SETTING / CONTEXT The bridge carries a 2-lane city street over a channelized stream in an early-20th century mixed-use section of Clifton. The street is lined with neighborhood commercial businesses. There are many late-20th century infill structures, like the large apartment complex on the downstream side, in the area that was originally developed with 2- and 3-story apartment buildings and frame duplexes. Both sides of the bridge are next to culverts, so the stream is not visible.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY According to the county engineer, the nucleus of the encased rolled stringer bridge on a concrete substructure was placed in 1905. It was altered in 1949 when an invert slab was added, and the fasciae were hidden by culverts. The inlet for the culvert is behind the buildings that front on the street the bridge carries. No bridge railings survive. The altered span, now part of a long culvert, is neither historically nor technologically significant.

DESIGNER/PATENT GARWOOD FERGUSON, CO. ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane street and sidewalks over a channelized stream in a mixed use area with a scrap metal yard, under which the stream flows, to the west and a county-maintained playground to the east. Multi-family housing is also in the vicinity. The bridge is one of several over the channelized stream that flows through Clifton.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased stringer bridge is supported on a concrete substructure that has been altered. The original railings were replaced with modern metal railings ca. 1957, and cut off walls were added at the abutment footings when an invert slab was placed in 1957. The west side of the structure has been enclosed. The channel is directed through concrete retaining walls lining the banks. An undistinguished example of a common bridge type, the span is neither historically or technologically noteworthy.

DESIGNER/PATENT WILLIAM L. WHITMORE **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in a mixed-use area just south of the central business district. The neighborhood is comprised of commercial, light industrial and multiple-unit dwellings, all of which lack integrity. To the west the brook flows in a deep channel, but culvertized under a swim club to the east. The bridge currently carries four lanes of city traffic and two sidewalks over the brook. When constructed, the bridge also carried two pairs of trolley tracks.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased stringer bridge designed by William L. Whitmore, former county engineer, replaced a structure destroyed in the 1903 flood. The bridge was altered in the Weasel Brook Improvement Project in 1957. Concrete alterations include cut-off walls in front of the footings, 2' thick walls in front of the abutments, and a slab form the channel invert 3' below the original floor as well as a new steel railing. The bridge is not historically or technologically significant.

DESIGNER/PATENT GARWOOD FERGUSON, CO. ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is part of a larger culvert that directs a minor stream through a residential area of primarily altered early-20th century dwellings and modern infill structures. The top of concrete culvert is utilized as a play yard on the east and a driveway/garage floor on the west. The bridge carries two lanes of traffic, two parking lanes, and two wide sidewalks over the channelized stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed, 79'-wide encased-stringer bridge was built in 1919 on stone abutments from an earlier span. It is finished with standard-design concrete parapets and paneled fascias. Culverts were added at each side of the bridge as part of the Weasel Brook Improvement program in 1957. The span is a representative example of a common county bridge type, and it is neither historically nor technologically distinguished.

CONSTRUCTION DT 1903 **ALTERATION DT** **SOURCE** COUNTY RECORDS

DESIGNER/PATENT WILLIAM L. WHITMORE **BUILDER** CYCLOPEAN IRON WORKS

SETTING / CONTEXT The bridge carries a two-lane road, utility pipes, and sidewalks over a minor river in a wooded setting in a mixed use area dominated by modern residential and corporate development. A late-19th or early-20th century brick factory is also near the bridge. The river has been dammed to create a mill pond.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 10/03/90

SUMMARY The 2-span continuous multi deck girder bridge on concrete abutments and pier was built to replace a 3-span arch bridge washed out in the 1903 flood. The built-up girders support transverse beams with concrete jack arches and a concrete deck. The original railings were replaced with the present one in 1948. The bridge is similar to 4 built over Molly Ann's Brook after the flood. They are more complete than this example, all evaluated by the SHPO as not eligible. This span is not distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a two-lane street, utility pipes, and sidewalks over a minor river in a mixed use area with residential, light industrial, and parks uses surrounding the span. Most of the structures are modern.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge was built in 2 sections. The original is a brick arch with a brick arch ring and ashlar spandrel walls that dates stylistically to ca. 1885. Footings for the arch are failing. The span was widened on both sides with encased stringers on concrete abutment extensions in 1925. The standard-design concrete balustrades also date to 1925. The 35' bridge has lost its integrity of design through deterioration. This is an altered example of what is not an uncommon bridge type in northern NJ.

DESIGNER/PATENT WILLIAM L. WHITMORE, CO. ENG **BUILDER** FRANK SISCO

SETTING / CONTEXT The bridge carries a 2-lane road and sidewalks over a minor stream in a casually landscaped Goffle Brook Park in Hawthorne Borough. The primarily open park is surrounded by homes from the last quarter of the 19th century to the present. A footpath that parallels the stream also is crossed by the road-carrying bridge. It is one of two bridges in the park. 1600105 is an undistinguished 1929 encased stringer.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased stringer bridge supported on a concrete substructure is nicely detailed with pebble-dash finish panels on the abutments, fascias, and posts. It is a relatively early example of what would become the most common mid-century bridge type in the state. Because of its age, custom detailing, and good state of preservation, the span is technologically and historically distinguished in the state context.

INFOR MATION

Bibliography:
Passaic County Engineer. Bridge File: 104.

Physical Description: The well-detailed 43'-long encased stringer bridge over a minor stream and parallel footpath in a small park is supported on a concrete substructure. The fascia stringers are finished with bush-hammer textured panels that match those that accent the posts of the concrete balustrades. The same detail is repeated at the corners of the abutments. The bridge carries a two-lane road and two sidewalks. It is well preserved.

Historical and Technological Significance: The bridge is technologically significant as an early and well detailed example of an encased stringer bridge. Built in 1904 to replace a bridge lost in the 1903 flood that claimed many bridges in the Paterson area, this span marks the transition from metal truss bridges to encased rolled stringers, the bridge type that would go on to dominate the 1915-1945 era (criterion C). In addition to being an early example of its type, the bridge is also well detailed, and its fine accenting with bush-hammer finished panels reflects the philosophy of the City Beautiful movement that encouraged aesthetic as well as functional considerations in civic projects. The custom detailing is in deference to the park setting of the span. It is located in Goffle Brook Park. The Passaic County engineers adopted stringer bridge technology earlier than most of their counterparts throughout the state.

Boundary Description and Justification: The bridge has been evaluated as significant on its own merits. The park in which it is located does not meet National Register criteria. It is small and does not have notable landscaping. The boundary is thus limited to the span itself.

DESIGNER/PATENT WILLIAM L. WHITMORE **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a two-lane city street and sidewalks over a stream in a mixed use area of altered late-19th and early-20th century houses, modern neighborhood commercial establishments, and some light industrial and service businesses. It does not have the integrity to be evaluated as a potential historic district. Haledon is a working-class borough that developed around silk mills.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 9/24/92

SUMMARY The thru girder with floor beams bridge has cantilevered sidewalks enclosed with the original picket fence-like railings. Concrete jack arches are set between the stringers. The bridge is similar in type and design to others built to replace spans over Molly Ann's Brook lost in the 1903 flood. This one is a representative example of what was a locally popular type. It is not individually distinguished and is not technologically innovative.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 9/24/92

SUMMARY The skewed 2-span bridge was built in two sections. The original portion is a brick arch with ashlar abutments and spandrel walls dating to 1875. It was widened in 1924 on the upstream side with encased stringers on concrete abutment and pier extensions. Both sides were finished with standard-design concrete balustrades. A metal walkway and steps provides pedestrian access to the bank on the upstream side. This appears to be a 1924 detail. The span is an late and altered example of its type.

DESIGNER/PATENT GARWOOD FERGUSON, CO. ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane road and narrow sidewalks over a minor stream in a late-20th century residential area with both single family homes and apartments. The setting is wooded.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed encased stringer bridge supported on a concrete substructure has been altered. The original balustrades/parapets have been replaced with steel railings ca. 1950, and modern beam guide rails have been welded to them. The fascia stringers are paneled. The bridge is an altered example of the most common pre-1945 bridge type in the county. It is not historically or technologically significant.

DESIGNER/PATENT GARWOOD FERGUSON, CO. ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane road and narrow shoulders over a channel of a minor stream. It is one span in a span-span structure that includes a pre-1900 stone arch span of less than 20'. The date of construction of the arch was not documented. The bridge is located in a sparsely developed wooded area at the head of the Clinton Reservoir.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The slab span on ashlar abutments was built in 1912 as a replacement span at an earlier 2-span stone bridge. What the original span was is not documented on the 1912 plans, but it was removed to accommodate the 20'-long 1912 slab span which was finished with pipe railings. Those railings were replaced with beam guide rail railings in 1955. The altered bridge is not technologically distinguished. The stone arch was not surveyed because it is less than 20' long and thus not a bridge.

DESIGNER/PATENT GARWOOD FERGUSON, CO. ENGINEER **BUILDER** F. W. SCHWIERS CO., NYC

SETTING / CONTEXT The bridge carries a two-lane street and narrow sidewalks over a mill tail race in the Society of Useful Manufacturers Historic District, the historic industrial heart of Paterson. The district, dominated by well-preserved late-19th century brick mills and works, was established in the 1790s and was powered initially by water from the Passaic River delivered thru a series of power canals and races used until about 1900. The power source was converted to electricity in 1912-14.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Society for Useful Manufacturers Historic District 04/17/1970. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased stringer bridge on an ashlar substructure with some concrete repairs was built at the end of the water-power era in the SUM district, but it does cross an original feature of the canal system. It is a noncontributing element based on its' alteration. The span was finished with a concrete balustrade with paneled end posts. One side has been replaced with ca. 1970 beam guide rail set between the original curved posts. The altered span is not distinguished in its own right.

INFOR MATION

Bibliography:
ONJH. National Register File: Passaic County; Paterson; SUM Historic District, 1970.
HAER. "Great Falls/ S U M Survey A Report on the First Summer's Work," 1973.
"The Great Falls Amble." Great Falls Preservation and Development Corporation, nd.

Physical Description: The undistinguished 45'-long encased stringer bridge is supported on ashlar abutments with some concrete repairs. The stone abutments predate this span. It was originally finished with a concrete balustrades with paneled end posts. One balustrade has been removed and replaced with modern beam guide rail.

Historical and Technological Significance: The altered encased stringer bridge is not individually technologically distinguished. It is a representative example of the most common pre-1946 bridge type in the state. But, it is located within the Society for the Establishment of Useful Manufactures Historic District, listed in the National Register and designated a National Historic Landmark district. Located at the great falls of the Passaic River, the S.U.M., as the area came to be known, was one of the pioneer industrial corporations in the county. It relied on a sophisticated system of canals to provide water to turn water wheels to power the factories. The three-tiered canal system that delivered water to turn the water wheels, the source of power for the factories and mills in the district, was in place in 1846.

The water powered industrial district was succeeded by the areas along the Erie and Paterson and Hudson railroads where more versatile steam was used to power the mills. By 1900 it was apparent that the individual water wheels using water from the raceway was generally less efficient than a central station generated by a hydroelectric plant on the river. The water wheels were inefficient unless all the mills on a raceway were operating at full capacity. Additionally, water was being used more in the industrial process, especially for the wet-spinning process at the Dolphin Jute mill and the Barbour flax-spinning mill, than in powering the mills. In 1910 the S.U.M. planned a hydroelectric plant to supply electricity to power the mills, and it was built between 1912-1914 closing the water-powered era in the district.

The bridge on Ellison Street crosses one of the historically significant power canals in historic district, but it was built after water had been superseded as the power source in the district. Thus it is not associated with the historical significance of the district. The bridge is also an altered structure and does not appear as it did in 1912 as a result of the loss of an entire balustrade line. Thus, the Ellison Street bridge is not historically related to the period of significance of the district. It is evaluated as a noncontributing resource.

SETTING / CONTEXT The bridge carries a 2-lane street, shoulders, and sidewalks over the Middle Raceway in the Society of Useful Manufactures industrial district (A National Historic Landmark) in Paterson adjacent to the Great Falls of the Passaic River. The district is dominated by well-preserved 3- and 4-story brick mid- to late-19th century mills and works that were originally powered by water supplied by the canal system. The area is of tremendous historical significance.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Society for Useful Manufacturers Historic District 04/17/1970. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Built to replace a span washed out in the 1903 flood, the reinforced concrete deck arch span with ashlar spandrel walls was built after plans by noted local builder F.R. Long. A cantilevered sidewalk was added to the west side in 1913, and both sides are finished with pipe railings dating to 1913. The bridge was built within the period of significance of the Society of Useful Manufactures district. It is also significant in its own right as an early local application of concrete technology.

INFOR MATION

Bibliography:

ONJH. National Register File: Passaic County; Paterson: Society for Useful Manufactures Historic District, 1970.
HAER. "Great Falls S U M Survey A Report on the First Summer's Work." 1973.
Passaic County Engineer: Bridge File #390.

Physical Description: The graceful one-span reinforced elliptical concrete deck arch bridge appears to have been built on the Monier reinforcing system. It is finished with ashlar spandrel walls which are probably concrete-backed. The spandrels are capped with blue stone and finished with pipe railings with handsome cast posts with ball finials. The railing is used elsewhere along the power canal. The sidewalk on the downstream side is original, but the cantilevered one on the upstream side was added in 1913. The bridge appears to be unaltered.

Historical and Technological Significance: The reinforced concrete deck arch bridge built in 1903 to replace a span lost in the October, 1903 flood, is individually distinguished as an early example of its type in the county. It was designed and built by noted local engineer and contracting firm F. R. Long of Hackensack (Bergen County) (criterion C). It is the second oldest bridge of its type in the county with only the 1898 3-span arch at West Broadway in Paterson designed by Edwin Thacher being older (1600017). Reinforced concrete was introduced into this country for bridge construction in the early 1890s, and it gained currency because of its low maintenance and economy in the first few years of the 20th century. By 1906 reinforced concrete arch bridges were common in New Jersey, but in 1903, the bridge type was just establishing its foothold. Fred R. Long (1850-1911), the designer and contractor, worked with Dean & Westbrook of New York City before going into business on his own in 1896. His office was in New York, but his yard and residence were in Hackensack, and he built many bridges in Bergen and Passaic counties.

In addition to its technological significance, the Spruce Street bridge is located within the Society for Useful Manufactures Historic District, listed in the National Register of Historic Places in 1970 and also designated a National Historic Landmark. Located at the great falls on the Passaic River, the area, with its sophisticated three-tiered power canal system, was developed as the model water-powered industrial district in the first half of the 19th century. Despite economic ups and downs, the district did prosper and remained active into the first decade of this century, although water power was less important as the 20th century approached. In 1910 the S U M developed plans to convert to hydroelectric power, and in 1912-1914 a hydroelectric generating plant was built at the falls. The electricity was used by the factories in the district. Thus, the Spruce Street bridge, which crosses the middle canal, was built at the end of the period of significance of the water-powered era. Because of its date of construction and state of preservation it is evaluated as a contributing resource.

Boundary Description and Justification: The bridge, while individually distinguished, is also evaluated as a contributing resource in the historic district based on its date of construction and appearance. It is situated well within the district, so the area on all quadrants are evaluated as significant.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 11/22/95

SUMMARY The 4-panel riveted Warren pony truss bridge with original knee brace-like verticals has rolled I-section floor beams placed on top of the lower gusset plates instead of being attached to them. This was done in 1954. No original plans survive, but physical evidence suggests that the unorthodox arrangement appears to be an original detail. The bridge is technologically significant as an example of experimentation inherent in hybrid truss designs. It is the only example of the floorbeam detail identified in the bridge survey.

INFOR MATION

Bibliography:
Passaic County Engineers Office: Bridge Files.

Physical Description: The 4-panel, 49'-long riveted construction Warren pony truss bridge is unusual in that the rolled I-section floor beams are placed above the lower chord and rest on the gusset plate at the lower panel points. There is no physical evidence to suggest this configuration is not original, but it appears that the flooring system was modified in 1954 when new rolled I-section floor beams and stringers, welded to the top flange of the floor beams, were placed. The depth of the original floor beams is not known. Welding the stringers to the floor beams distributes live load throughout the truss. The original outriggers are connected to the top flange of the replacement floor beams that extend beyond the panel point, and they serve to brace the top chord. The top chord members are composed of toe-in channels with lacing on the upper face and battens on the bottom. Cover plate is used only at the connection between the inclined end posts and the bearings. The diagonals and bottom chords are a pair of angles with battens. The stone abutments have been raised or rebuilt with concrete extensions upon which the stringers and the small, end-panel floor beams bear. The pipe railings in the roadway faces of the trusses are attached by the original cast brackets. There is no scaring to indicate that the railings were ever in a different position. Aside from the new flooring system, the bridge appears to be well preserved.

Historical and Technological Significance: The undocumented Warren pony truss bridge is technologically significant as an example of a hybrid design. It is dated ca. 1910 based on the fact that it is of riveted construction, and it is known from the County Engineer's records that other pony trusses of this design were built in Passaic County. No plans for the bridge survive. The span represents the experimentation inherent in hybrid truss designs as thoughts on improved economy of material and transfer of loads were worked out in variations on the standard Pratt and Warren truss designs (criterion C). Nothing is known about the designer or the intent of the unusual design, but it does conform to fact that placing floor beams above the lower chord provides a stiffer truss. It also appears that the use of the outriggers and the wide spacing of the diagonals was an attempt at economy and efficiency.

The flooring system (floor beams, stringers, and deck) were replaced in 1954, and the composition and dimensioning of the original is not known. There is no evidence on the trusses themselves to suggest, however, that the unusual configuration of the truss dates from 1954. The pipe railings at the inside faces appear to have always been in their present location. They and their mounting brackets appear to be original.

Thus the bridge survives as one of the most unusual Warren pony truss designs in the state. It reflects idiosyncratic thinking about metal truss bridges. What is noteworthy about this span is that it is applied to riveted bridges. Hybrid designs are more often associated with the early days of metal truss bridge development and pin-connected spans rather than ones with riveted field connections that date to after 1895. By that time the efficiency and economy of the Pratt and Warren trusses with floor beams placed below the bottom chord was well established and acknowledged.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. Therefore, the boundary is limited to the substructure and superstructure. The substructure is noteworthy on this span because it was modified to accommodate the present flooring system.

SETTING / CONTEXT The bridge carries a 2-lane road over an outlet from a recreational lake in a low-density wooded residential area initially developed in the 1920s as a cottage community. Some 1920s and 1930s rustic-style cottages remain, but the area is dominated by modern year round homes. Packanack Lake was created by an earth dam located parallel to the road. The overflow is at one corner of the lake. A sidewalk is carried on a separate stringer span on the lake side of the bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge is composed of 2- and 4-span rolled I section multi-girders supported on a concrete substructure. The lake side girders are 4 span while those on the downstream side are 2 span. The girders support transverse beams that support the rolled stringers and corrugated deck pans placed in 1952. The bridge is framed by modern guide rail railings. The sidewalk is a separate 2-span stringer structure added in 1965. Sluice gates have been removed. The span is not technologically distinguished.

SETTING / CONTEXT The viaduct carries a 2-lane road over the Wanaque Reservoir, a project started in 1923. The bridge was designed by and built in the 1920s for the North Jersey Water Supply Commission, and it survives in its original context.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Agreed Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 7-span T-beam bridge on a low rise concrete substructure is finished with a standard-design concrete balustrade. The west sidewalk was eliminated in 1974 to increase roadway width. The bridge has historical value as one of the structures built as part of the development of the potentially historic reservoir that provides water to the Paterson-Newark area, but it is a technologically undistinguished and altered example of common bridge type. It is not noteworthy in its own right.

INFOR MATION

Bibliography:
North Jersey Water Supply Commission. 1925 Report.

Physical Description: The 505'-long, seven span bridge is a concrete T-beam structure with a concrete substructure. It is finished with a standard-design concrete balustrade with paneled end sections. The bridge originally had concrete sidewalks on both sides, but in 1974 the south sidewalk was removed and the area became part of the roadway. The roadway width was increased from 16'-6" to 20'-1". Otherwise, the bridge appears to be unaltered.

Historical and Technological Significance: The seven-span concrete T-beam bridge built in 1926-27 is not distinguished in its own right. It is a representative example of a common bridge type. It is evaluated as significant because it was built by the North Jersey Water Supply Commission as part of the 1920s development of the Wanaque Reservoir, a major engineering project to address the issue of a safe water supply for the Paterson and Newark areas (criteria A, C). The reservoir appears to be a potential National Register historic district based on its social history and engineering significance. The controversial project involved securing the water rights to Greenwood Lake and then to planning to relocate roads and other features that would be under water once the concrete Raymond Dam across the Wanaque River was completed.

Several routes across the reservoir to link Ringwood/Greenwood Lake Road and Stonetown Road were contemplated, and the present route of West Brook Road was selected to minimize the cost of bridge construction. Several bridge types, including concrete arch spans and steel bridges, were studied, and it was decided that when factoring in both cost of construction and maintenance, the concrete girder and pier bridge was the best technology for the crossing. Because the bridge was one of the prominent structures in the Wanaque project, "the element of appearance warranted and was given consideration." That "consideration" is reflected in the detailing of the concrete balustrades.

The dam, water control-related buildings at the base of the dam, and the West Brook Road bridge all retain their original appearance and function.

Boundary Description and Justification: The bridge is located within a potential historic district. Because of its situation within the potential district, the bridge and its surroundings are evaluated as significant.

DESIGNER/PATENT CORNELIUS VERMEULE, CONS. ENG. **BUILDER** WINSTON & CO., INC.

SETTING / CONTEXT The bridge carries a 2-lane street and sidewalks over a river in a wooded residential area that dates to the 1960s. The Federal-style house adjacent to the bridge was reportedly moved to the site in the 1960s or 1970s. The span is one of several bridges built on state highways as part of the abandonment agreement of the Morris Canal, which was closed to navigation in 1924 and subsequently filled in many areas.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Morris Canal. 10/01/1974. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The elliptical deck arch bridge with a vertical crest to the roadway and paneled parapets set between massive end posts is a late example of the bridge type. It was built in 1928 as part of the 1924-28 Morris Canal abandonment that was designed and directed by consulting engineer C. Vermeule. Closing the 88-mile long canal involved filling most of the canal and buildings some bridges, culverts, and dams. This span is one of the major bridges, and it crosses a river used for canal navigation. The bridge is not individually eligible for listing in the National Register, but is a contributing element of the Morris Canal Historic District eligible under Criteria A and C.

INFOR MATION

Bibliography:
Vermeule, C., Jr. Morris Canal and Banking Company Final Report of Consulting and Directing Engineer. 1929.

Physical Description: The well-proportioned 92'-long reinforced concrete deck arch bridge with a vertical profile is detailed with massive end posts that mark the limits of the clear span. They are paneled to match those used to give scale to the concrete parapets. The approaches are marked by a similar paneled parapets. The bridge appears to be unaltered.

Historical and Technological Significance: Built in 1928 as part of the of the Morris Canal abandonment, the reinforced concrete deck arch bridge is historically significant because of its association with the abandonment campaign. The ambitious abandonment was designed and directed by Cornelius C. Vermeule, a consulting engineer from East Orange, New Jersey who was hired by the Morris Canal and Banking Company board of directors. The project closed and disposed of the 88-mile long right-of-way and all the structures related to the canal that was completed in 1824 between Phillipsburg and Elizabeth and later Jersey City.

Under an 1836 agreement with Revolutionary war officer William Colfax, the Morris Canal and Banking Company built and maintained a bridge near this crossing. The Ramapo River was canalized for navigation at this point. When it became necessary to replace the narrow, wooden bridge with a permanent structure as part of the abandonment, the residents requested that the new bridge be located downstream so that approaches and roadway width could be improved. Passaic County contributed $11,500. to the building of the new span, and construction began in 1928. Thus the 1928 span, known as the Colfax Bridge, stands as witness to the canal that was one of the important early transportation networks in the state. Although the bridge is not original to the canal, it is one of the major structures built as part of the elimination of the canal and is thus historically linked to one of the significant engineering feats in the state (criterion A). The bridge is not technologically distinguished, but it is significant for its association with the history of the Morris Canal and the statewide improvement campaign to remove it. The Colfax Bridge is one of seven that were built under the abandonment campaign.

Boundary Description and Justification: The bridge is evaluated as significant because of its historical association with the Morris Canal and the abandonment campaign. The canal right-of-way, which is the river at this location, was listed in the National Register 10/1/74, but none of the structures that intersect the historic right-of-way were addressed in the nomination. The boundary of this resource is limited to the structure itself. It should be noted that this bridge is not on the location of the historic one it replaced. The original crossing is upstream from this span.

CONSTRUCTION DT 1924 **ALTERATION DT** **SOURCE** INSCRIPTION

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries two lanes of one directional traffic of a divided state road over a meandering river in a mixed use area that includes a range of buildings types and uses from a mid-19th century school converted to a restaurant to modern service stations. Opposing traffic is carried over the same feature on a post-1946 bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 4/10/90

SUMMARY The skewed two-span encased stringer span is supported on a scored concrete substructure. It is framed by a standard-design balustrade with end posts inscribed with the date and original route designation (8). The span is a representative example of the most common first half of the 20th century bridge type in the county, and it is neither historically nor technologically distinguished.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 02/08/90 02/21/97, Letter 6/30/95.

SUMMARY The 5-span open spandrel ribbed arch bridge, one of 10 designed between 1929 and 1939 by the bridge division under the direction of Morris Goodkind, is a large and well preserved example of the technologically noteworthy bridge type. They combine economy of material with great elegance and were selected by the state for highly visible large crossings. The bridge is an important example of its type.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries a guide rail-divided, 4-lane, limited access highway and narrow sidewalks over two lanes of one directional (westbound) traffic of another state highway. The interchange was built as part of the a road improvement campaign to ease access to the Lincoln Tunnel, opened in 1938. The highways pass through mixed use areas with a predominance of modern commercial establishments.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Finding 2/21/97.

SUMMARY Built as part of a breakout of a new short route to help access the Lincoln Tunnel, the skewed, encased stringer bridge is supported on concrete abutments accented with shallow panels and corner pilasters. The standard-design balustrades have paneled posts. The bridge is not technologically distinguished, and the interchange of which it is a part is not innovative or historically noteworthy. It is a typical state design solution to common traffic engineering problems in northern New Jersey.

SETTING / CONTEXT The bridge carries 3 active sets of railroad tracks over a barrier-divided, 4-lane, limited access highway and elevated sidewalks in a mid- to late-20th century industrial area.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Finding 12/07/89 2/21/97.

SUMMARY The 2-span encased thru girder with floor beams bridge is supported on a concrete substructure. It is composed of 5 girders with concrete encasing the entire floor system. Original concrete light standards have been removed. The plain concrete parapets include the outside girders. Grade-level sidewalks are enclosed by pipe railings. The bridge with a concrete deck is a representative example of a common type. The span is neither historically nor technologically distinguished.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries a barrier-divided, 4-lane, limited access highway over a 2-lane street and sidewalks in a ca. 1900 residential and neighborhood commercial area of Clifton. The buildings are altered. US 46 was originally developed as Route 6 linking the George Washington and Ben Franklin bridges. It was upgraded in this area in 1939.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Finding 2/21/97.

SUMMARY The one span open spandrel arch bridge with spandrel columns and stepped pilasters with tile decoration is the shortest of the approximately 10 bridges of the type designed by the state between 1929 and 1939. It is one of 3 in the county. It is significant because it is a well-preserved example of a technologically important bridge type that is not common. The bridge reflects the successful integration of aesthetics and innovative engineering.

INFOR MATION

Bibliography:
NJDOT. Plan File; 1607168.
Condit, Carl. American Building Art 20th Century. 1960.
Hess, Jeffrey & Frame, Robert. "Wisconsin Stone Arch and Concrete Arch Bridges." 1986.
Plowden, David. Bridges: The Spans of North America. 1974.

Physical Description: The 82'-long single span open spandrel arch bridge of reinforced concrete is well proportioned and well detailed. It is finished with spandrel columns and Modern-style stepped pilasters that define the span limits. The outside face of the end posts is decorated with a mosaic tile seal of the state. The deck is concrete, and the wearing surface is bituminous concrete. Sidewalks are framed by standard-design concrete balustrades. The bridge appears to be well preserved.

Historical and Technological Significance: The concrete open spandrel arch bridge built in 1939 is significant as a well-preserved example of the technologically noteworthy and aesthetically impressive works of Morris Goodkind (1869-1968) produced throughout his career as State Bridge Engineer (Criterion C). It is one of approximately 8 open-spandrel arch bridges in New Jersey, a bridge type that defines the highest level of refinement in reinforced concrete arch technology. It is one of three on NJ 46 in Passaic County (1607168, 1607158). The well-preserved bridge represents Goodkind's emphasis in the New Jersey State Highway Department Bridge Division to create aesthetically pleasing concrete structures prior to World War II. The moldable qualities of the material were used to create an architectural masterpiece at the same time that its structural qualities were used to efficiently carry a major highway across feature requiring a long clear span. The reinforced concrete arch was capable of relatively long spans while providing graceful and dynamic forms.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type. A massive structure, the open spandrel arches of that structure span 233 feet with virtually no steel reinforcement in the two ribs. In the first two decades of the 20th century, railroads began using reinforced concrete to construct large viaducts across rivers and valleys to eliminate steep grade changes. The length and number of spans increased to create massive structures that dominated the landscape. The Tunkhannock Viaduct (completed 1915 and designed by A. Burton Cohen, 1883-1956) of the Delaware Lackawanna & Western RR in Nicholson, Pennsylvania remains one of the greatest bridges in America. It is a ten-span open spandrel reinforced concrete arch, 2375 feet in total length, each span 180 feet in clear span, and rising 240 feet above the creek bed in the valley floor.

The US 1 Bridge, completed 14 years later in 1929, but comparable in size and beauty, was the first of Goodkind's open-spandrel concrete arch bridges in New Jersey. The bridge type was repeated with equal success at major crossings on major roads throughout the northern half of the state through the 1930s. NJ 46 was upgraded in the late 1930s to serve as a major link between the Hudson River crossings into Manhattan and the west portion of the state, especially Morris and Passaic counties.

Morris Goodkind, designer of the bridge, was a graduate of Columbia University. He worked for the New York City Public Service Commission in the development of the subway system before working on bridge designs for engineering firms and Mercer County, NJ. In 1922 he joined the New Jersey Highway Department, and became the Chief Bridge Engineer in 1925, a post he held through 1955 when he retired to private practice.

The 1920s and 1930s were a time of great expansion of the state's highway system which required many bridges to be built. Goodkind emphasized the need for aesthetically pleasing as well as structurally sound bridges. He brought in Arthur Lichtenburg to develop an architectural section in the Bridge Department. Many of the grade elimination bridges of the 1930s and 1940s in congested areas were detailed with Moderne and Deco pilasters and entablature due to the influence of Goodkind and Lichtenburg. The same structures had encased stringers, the most common type built during Goodkind's term. He emphasized the encasement for protection of the steel from the elements, a valid assertion considering the number and condition of such structures remaining in New Jersey.

A. G. Lichtenstein & Associates, Inc. performed initial survery.
NJDOT updated data 03-01-2001.

Correspondence.Unit@DOT.State.NJ.US
November 12, 2002

While working for the state, he served as a consultant on bridge construction for the War Department. Upon his retirement as Chief Bridge Engineer, Goodkind became a consultant with the firm of Goodkind and O'Dea in Manhattan. He was internationally known and respected for his bridge engineering. He had been active in local and national engineering societies, and won several awards for the designs of bridges.

Goodkind was awarded the Phoebe Hobson Fowler Architectural Award by the American Society of Civil Engineers for the design of the US 1 bridge. To recognize the contribution which Goodkind made to the State of New Jersey, the name of the bridge was officially changed from the College Bridge to The Morris Goodkind Bridge on April 25, 1969, following his death the previous September.

Of the approximately 8 pre-1946 open-spandrel arch bridges in the state, all but one (1213150) have been evaluated as significant.

Boundary Description and Justification: The bridge is evaluated as individually significant, and the boundaries are thus limited to the span itself. NJ 46 was improved in the mid- to late-1930s as a major artery handling Morris County and Passaic County traffic approaching the Hudson River crossings. The road is dominated by what by the mid-1930s were standard solutions to common engineering problems.

 # SPANS 1 **LENGTH** 40 ft **WIDTH** 36.3 ft

CONSTRUCTION DT 1915ca **ALTERATION DT** **SOURCE** STYLE

DESIGNER/PATENT ERIE RR OFFICE OF ENGINEER **BUILDER**

SETTING / CONTEXT The bridge carries a 2-lane road with sidewalks over one railroad track. The area is dominated by light industrial and commerical establishments. The bridge crosses the Erie Railroad's Newark Branch that was initially developed in 1869.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The ca. 1915 skewed slab bridge is supported on a substructure composed of the random ashlar abutments from a previous span and concrete extensions with wingwalls. The bridge is finished with a concrete parapet accented with contrasting bush-hammer finish panels. No plans for the bridge appear to survive. It is dated ca. 1915 based on its type and design. It is not historically nor technologically distinguished.

NEW JERSEY HISTORIC BRIDGE DATA

STRUCTURE # 1700199 **CO** SALEM **OWNER** COUNTY **MILEPOINT** 0.0
NAME & FEATURE INTERSECTED MILL ROAD (CR 642) OVER OLDMANS CREEK **FACILITY** MILL ROAD (CR 642)
TOWNSHIP OLDMANS TOWNSHIP
TYPE SWING SPAN **DESIGN** CENTER BEARING **MATERIAL** Steel
 # SPANS 2 **LENGTH** 170 ft **WIDTH** 16.4 ft

CONSTRUCTION DT 1906 **ALTERATION DT** 1976 **SOURCE** NEWSPAPER
DESIGNER/PATENT WILLIAM M. CARTER **BUILDER** NJ-WVA BRIDGE COMPANY

SETTING / CONTEXT The single-lane bridge spans a tidal estuary in a broad wetlands just north of the small 19th-century village of Pedricktown. The swing span's central pier sits on an island in the middle of Oldmans Creek and the moveable span crosses over only one of the creek's channels. Pedricktown has some excellent examples of 19th-century vernacular domestic and commerical architecture but has too many modern intrusions for a historic district.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Not Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Originally a center-bearing truss swing span with a rivet-connected Warren pony truss approach span with masonry abutments and reinforced-concrete piers, the bridge has been so altered that it has lost its historical and technological significance. The truss approach span was replaced with the current steel-stringer span in 1976, and the swing span was reinforced and fixed in place. The operating mechanism was removed as were the wedges and toe locks.

INFOR MATION

SOURCES:
Biographical, Genealogical, and Descriptive History of the First Congressional District of New Jersey. New York: Union Publishing Co., 1900.
Gloucester County Board of Freeholders. Minute Books. Dec. 21, 1905.
Hool, George A. and W. S. Kinne, eds. Movable and Long Span Bridges. New York: McGraw-Hill, 1923.

Salem County Engineer. Plans and Bridge Cards.
Salem Sunbeam. Nov. 22, 1905.
Salem Standard and Jerseyman. Dec. 15, 1905, and Jan. 17, 1906.

PHYSICAL DESCRIPTION The bridge is a 103'-long, single-lane, wood-decked, center-bearing, steel through truss swing span with a 67'-long steel stringer approach span on the south side. The main span of nine panels with a central tower has a lower chord of channels with lacing, and an upper chord of channels with lacing and a cover plate. The verticals and diagonals are either laced or battened channels and angles. The bridge has lower lateral bracing rods with turnbuckles. The central tower has latticed portals, lateral tie rods, and a makers plaque. The truss system has not been significantly altered except for some repairs to the tower braces, and the addition of some reinforcing plates.

The swing span has been rendered inoperable and most of the operating mechanism has been removed. It is a center-bearing type, originally hand-powered by a crank attachment inset in the deck. The crank turned the pinion gear against the circular rack mounted on top of the center pier. A box-shaped system of four girders with four balance wheels supported and balanced the bridge's weight on the center pier when the bridge was in the open position. The girders and rollers are extant. In 1988, the bridge's end bearings, originally rollers designed to lift the bridge in the closed position and lock it in place, were replaced with elastometric pads on concrete pedestals.

The approach span was originally a 7'-deep, riveted Warren pony truss. In 1975 a dump truck broke through the deck and destroyed the truss. It was replaced with a steel-stringer span.

The substructure consists of masonry abutments with concrete reinforcing and repairs. The piers are reinforced concrete with metal sheeting. The bridge's timber pile fenders are in a deteriorated condition.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE The swing span over Oldmans Creek has been significantly altered. The bridge was a representative example of a popular early-20th century movable-span technology. A better example of the bridge type is New Bridge over Alloways Creek (1905, No. 1701399) in Salem County. New Bridge is built upon similar specifications and is better preserved.

A bridge has spanned Oldmans Creek between Salem and Gloucester Counties at Pedricktown since the early 19th century. In 1904, the Salem County Board of Freeholders hear a report from the local residents that the old wooden draw had become unsafe. since the bridge spanned the creek between the two counties, the Salem County Freeholders determined to advise the Gloucester County Freeholders of the need to replace the bridge. Usually the two counties shared the cost of upkeep and repair of bridges on their shared border. In the case of the Pedricktown Bridge, however, the Gloucester County Freeholders refused to authorize the replacement of the bridge because the Bridge Meadow Company on Oldmans Creek, whose majority members were Salem County residents, had not maintained the banks and dikes along Oldmans Creek in sufficient repair to prevent flooding of Mill Road. In late 1905, the company made arrangements to repair the banks and dikes; subsequently, the two counties came to an agreement to share the cost of building a new steel draw.

The specifications for the new bridge were prepared by Woodbury's city engineer, William Carter, a self-taught professional with a sideline in insurance and real estate. At $11,300, the New Jersey-West Virginia Bridge Company was the lowest bidder for the job. No other bridges built by the NJ-WV Bridge Co. have been identified, although it seems likely that the company was a merger or buy-out of the financially-troubled New Jersey Bridge Co. of Manasquan by the West Virginia Bridge Co. of Wheeling. In 1905, the New Jersey Bridge Co. had constructed the New Bridge over Alloways Creek in Salem County, a span very similar to the Pedricktown Bridge over Oldmans

Creek.

The Pedricktown Bridge over Oldmans Creek is not an example of innovative technology. Center-bearing swing spans were popular in the first decades of the 20th century for applications where large channel widths and long periods of interruption to vehicular traffic were not major considerations. The replacement of the approach span and the disablement of the swing span make it a poor candidate for preservation.

SETTING / CONTEXT The one-lane bridge spans the spillway from Memorial Lake in Memorial Park on the south side of Woodstown. The borough created the lakeside park in the early 1920s to commemorate WWI. The area surrounding the park is residential (c. 1850-1950). The bridge is structurally associated with the U-shaped spillway/dam that creates Memorial Lake. The center of the spillway once had a fountain. The park does not appear to be NR eligible.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span, T-beam bridge with concrete balustrades and substructure is representative of at least 17 examples of the bridge type built in the county between 1917 and 1944. Its setting in a 1920s memorial park is well preserved, but the bridge itself is technologically and historically undistinguished. Utility pipes and a steel platform have been added. The bridge's local historic value is not sufficient to meet National Register criteria.

INFOR MATION

SOURCES:

Combination Atlas and Map of Salem and Gloucester Counties. Philadelphia: Everts and Stewart, 1876.
Salem County Board of Freeholders. Minute Books. May 10, 1922 and Nov. 15, 1922.
Ketchum, Milo S. The Design of Highway Bridges of Steel, Timber and Concrete. New York: McGraw-Hill, 1920.
Shuck, Albert C., et. al. "A Story of Salem County." Typescript. Salem City Public Library. 1938.

PHYSICAL DESCRIPTION The two-span, concrete T-beam bridge has concrete balustrades and substructure. A T-beam bridge is characterized by reinforced concrete beams with T-shaped reinforcing bars. Structurally associated with the bridge is a stepped, semi-circular spillway/dam with a central water fountain display. Molded into the spillway walls are the words "Memorial Lake." The dam/spillway creates Memorial Lake, the central feature of Woodstown's Memorial Park. The bridge has not been significantly altered, but the spillway and fountain are in poor repair. A utility pipe has been suspended from the bridge, and a steel platform erected over the spillway next to the south abutment.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE The Memorial Lake Bridge is one of the most distinguished of over 15 similar, short-span T-beam bridges built in Salem County between 1917 and 1944. It is structurally associated with a spillway/dam, and is located in Woodstown's largest city park. The T-beam was a standardized bridge design that came into wide use in Salem County during the tenure of the county's first professional engineer, Howard B. Keasby. The bridge is one of the best examples of a bridge type of local historic importance, but it is not significant enough to merit National Register recognition.

Shortly after WWI, Woodstown bought the Memorial Lake property for a city park, commemorating its wartime veterans. The property had formerly been the site of a grist mill with mill pond. An 1876 map shows a bridge spanning the mill pond spillway and a grist mill downstream from the bridge. The mill buildings no longer exist. In 1922 the worn-out wood-stringer bridge was replaced with a new T-beam bridge. The county was in the midst of a campaign to replace many of its wood bridges with concrete or steel. The plans for the Memorial Lake Bridge included "two spans of 30', a gravel roadway 2' higher than the old bridge, and a tumbling dam." The bridge was to be paid for by the county, and the "tumbling dam" by the Woodstown Chamber of Commerce. The contract to build the new bridge was awarded at a price of $13,240.47 to Kuchar Brothers, contractors from Spring Valley, New York. Kuchar Brothers also held large contracts for improvements to the newly-created state highways in Salem County.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span T-beam bridge with concrete balustrades and reinforced-concrete abutments is a representative example of at least 17 similar T-beam bridges built in Salem County between 1917 and 1944. Builder Samuel Campbell of Bridgeton constructed the bridge, which according to county records replaced a timber-stringer bridge. The bridge is not historically or technologically significant.

CONSTRUCTION DT 1930 **ALTERATION DT** **SOURCE** COUNTY ENGINEER

DESIGNER/PATENT UNKNOWN **BUILDER** C. FISKE CAMPBELL

SETTING / CONTEXT The two-lane, three-span bridge crosses Alloways Creek within the village of Alloway. The village contains many excellent examples of mid-nineteenth and early-twentieth century vernacular architecture. The village appears to have enough architectural cohesiveness to be considered for National Register District status but the bridge falls outside of the period of significance (c. 1830-1915).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span, steel-stringer bridge has concrete balustrades on the center span and paneled parapets on the approach spans. It has encased fascia and reinforced-concrete substructure. It is one of at least 8 similar steel stringers built in Salem County between 1930 and 1941. Lateral vertical bracing has been added between the stringers. The span is a representative example of a common pre-1946 bridge type in New Jersey and is not historically or technologically distinguished.

SETTING / CONTEXT The two-lane, two-span bridge is located within the boundaries of wooded Parvin State Park (c. 1933-41). It is structurally associated with the circular spillway and dam that creates 4/5 mile-long Parvin Lake, the park's central recreational feature. On the lake's north shore is a bath house and beach, and on the south nature areas, log cabins, and campgrounds. The early south Jersey park was developed as a CCC project.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Potential Parvin Lake Park Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 11/22/95

SUMMARY The 2-span concrete slab bridge with concrete balustrades and substructure ranks as one of the most architectonic of its type in the region. The well-proportioned upstream wing walls with parapets set off the bridge from the circular concrete spillway/dam. Earlier and more historically distinguished examples of concrete-slab bridges exist in the state (e.g. 0809L02). Although not individually significant, the bridge is locally significant as a contributing resource to a potential historic district: the CCC-developed park.

INFOR MATION

Shuck, Albert C., et. al. "A Story of Salem County." Typescript. Salem City Public Library. 1938.

PHYSICAL DESCRIPTION The 54'-long, two-span concrete-slab bridge with concrete balustrades, concrete abutments, and concrete cutwater pier survives in a good state of preservation. The large upstream wing walls have concrete parapets with horizontal scoring. The parapets meet the bridge's balustrades and form a continuous railing for pedestrians. Extending between the upstream wing walls is the semi-circular concrete spillway/dam that forms Parvin Lake.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE The concrete slab bridge is one of the largest and most distinguished of its type in the region. It is a central feature of Parvin State Park, one of the first state parks in South Jersey. It is also an excellent example of a New Deal public works project. The bridge is well-proportioned to provide bridge traffic with a view of the water cascading over the semi-circular spillway/dam.

A bridge has stood at the site since at least the mid-19th century. In 1867 Lemuel Parvin bought the surrounding property and constructed a saw mill, dam, and pond. In 1923 the county replaced the preexisting wood-stringer bridge with a concrete T-beam bridge. At the same time they built a concrete dam/spillway. In the 1920s the bridge was known as Ackley's Mill Pond Bridge after the then current owner of the saw mill. No physical above-ground evidence of the saw mill and its associated structures remains.

In 1933 the mill site and pond were acquired by the New Jersey Department of Conservation and Development as a Civilian Conservation Corps (CCC) camp and state park. The CCC was a New Deal work-relief program for young men. By June 1933, the CCC had 1,300 camps nation-wide and employed 300,000 men. The CCC did much to improve national and state parks. At Parvin State Park the Corps cleared picnic grounds, built cabins and a bath house, constructed roads and bridges, and dredged the pond. Most of these improvements still exist within the park. In the flood of September 1940, the 1923 T-beam bridge and spillway were destroyed. CCC workers built the new two-span concrete-slab bridge with materials provided by the county. The bridge was completed in August 1941.

SETTING / CONTEXT The two-lane bridge spans a wide but shallow stream in a forested section of the DEP's Union Lake Wildlife Management Area located near the Maurice River in eastern Salem County. The surrounding area is undeveloped.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The unaltered three-span bridge with reinforced-concrete substructure has T-beam approach spans and a steel-stringer center span with encased fascia stringers. The approaches have paneled concrete parapets and the center span has concrete balustrades. T-beams and steel-stringers are two common bridge types and account for 44 of the 56 existing pre-1946 bridges in Salem County. The bridge is not historically or technologically distinguished.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge is a center-bearing, steel-truss swing span with modified Warren pony truss approach span. The bridge was hand operated and the mechanism is in place, although the bridge has not been opened since the mid-1960s. It has ornamental finials, lattice work, and plaque on the tower. The bridge is the best example of its type in the southern part of the state. It is one of a small handful of documented surviving NJ Bridge Co. bridges in the United States.

INFORMATION

SOURCES:
Hool, George A. and W. S. Kinne, eds. Movable and Long Span Bridges. New York: McGraw-Hill, 1923.
Manasquan Chamber of Commerce. Manasquan, New Jersey. 1962.
Manasquan Historical Society. "New Jersey Bridge Company File."
Salem County Board of Chosen Freeholders. Minute Books. 1905.
Salem County Engineer. Plans and Bridge Cards. #1399.
Salem Sunbeam. Aug. 11, Aug. 16, and Sept. 20, 1905.

Physical Description: The bridge is a 110'-long, single-lane, wood-decked, center-bearing, steel through truss swing span with a 37'-long, 3-panel, riveted Warren pony truss span on the north side. The main span is a 9-panel truss with a central tower. At the first panel it is 8'-deep, and at the tower it is 22'-deep. The lower chord consists of angles with lacing, and the upper chord of channels with lacing and a cover plate. All connections are riveted. The verticals are laced angles or channels, and the diagonals are channels with battens. The central tower has latticed portals, lateral tie rods, and two of four original urn-shaped finials. Plaques on the tower portals read "1905. Built by New Jersey Bridge Co., Manasquan NJ."

The swing span is inoperable, but the operating mechanism remains extant. It is a center-bearing type, hand-powered by a crank attachment inset in the deck. The crank turned a pinion gear against a circular rack. The rack is mounted to the top of the center pier. The bridge was designed to open in either direction, and turns upon a center bearing. A box-shaped system of four girder with four balance wheels supported and balanced the bridge on the center pier when the bridge was in the open position. The south end of the bridge rests on steel rollers with axles perpendicular to the length of the bridge. They were hand operated by levers and designed to lift the bridge in the closed position, lock it in place, and provide it with a footing on the abutment. The swing span has timber pile fenders. It provided a 42'-channel to river navigation, and last opened in the mid-1960s.

Numerous alterations have been made to the substructure and the approach span, but none seriously compromise the bridge's overall integrity of design. The original piers and abutments were masonry. In 1925 the center pier was widened and reinforced with concrete. In 1942 the south abutment was rebuilt with concrete, and in 1957 the abutments were raised by approximately 12 inches. In 1966 the northern pier and abutment were reinforced with concrete. In 1976, following a vehicular accident, an end post and portion of the lower chord of the west side of the pony truss were replaced and repairs made to the panel points. A vertical on the east side of swing span was replaced, and the lattice railings were removed and beam guard rails added. In 1979 the approach span was strengthened with the addition of longitudinal steel stringers that effectively relieved the pony trusses of load bearing responsibility. In 1991 the single-lane bridge was closed to vehicular traffic due to safety concerns and structural inadequacies.

Historical and Technological Significance: The bridge is one of the few documented surviving examples of a bridge constructed by the New Jersey Bridge Company of Manasquan. Although never recognized as a major national bridge builder, the company was a significant in-state manufacturer of highway bridges. The swing span over Alloways Creek is a good representative example of a popular 20th-century movable span bridge technology that is becoming increasingly rare. It retains integrity of design and of setting.

A bridge has spanned Alloways Creek at the site of New Bridge since the early-19th century. In 1905 the Salem County Board of Freeholders decided to replace the worn-out wooden draw bridge with a new steel swing span. They drew specifications for the new bridge and advertised for bids. At a price of $10,200, the NJ Bridge Co. was the lowest bidder of seven companies.

The NJ Bridge Co. operated from 1890 to 1907. The company was started by two gentlemen from Canton, Ohio, Mr. Wyckoop and Mr. Braly. The built a 300'-deep, 100'-wide shop in Manasquan on Atlantic Avenue, adjacent the railroad tracks. At the height of their operation they employed 15 to 20 draftsmen and 100 men in the fabricating shop. A local history claims that the company "was the largest individual manufacturing facility ever to have existed in Manasquan." In 1904-1907 the company ran into financial difficulties after securing the contract to build a large swing span, Long Bridge over the Fore River, in Portland, Maine. Unable to meet its obligations and material deliveries, the company went out of business in 1907. The company went into bankruptcy at the end of an era of small, regional, independent, bridge manufacturers. The Manasquan Historical Society owns a series of photographs illustrating the company shops. No

known company records survive.

According to a local history, many of the bridges built by the NJ Bridge Co. were erected in Middlesex and Monmouth Counties. The company had some national contracts; in addition to the Portland Bridge, which has been demolished, a Pratt truss has been identified in Grand Rapids, Michigan. It too is scheduled for replacement. In Salem County a slightly larger, less well-preserved, and similar movable bridge spans Oldmans Creek near Pedricktown (1700199). According to local records, in 1906 the New Jersey-West Virginia Bridge Co. constructed the Pedricktown Bridge based upon the same specifications prepared for the swing span at Alloways Creek. The relationship of the NJ Bridge Company to the NJ-WV Bridge Company is not known, except that it seems a reasonable assumption that the latter was a merger or buy-out intended to save the former from bankruptcy.

Boundary Description and Justification: Although the unspoiled setting contributes to the character of the well-preserved bridge, it is the structure itself that is evaluated as significant. The boundary is thus limited to the bridge, substructure and superstructure, of the approach span and the movable span themselves.

DESIGNER/PATENT PA-READING SEASHORE RAILROAD **BUILDER**

SETTING / CONTEXT The skewed, two-lane bridge crosses the Salem Branch of Conrail, the former Pennsylvania-Reading Seashore Lines Railroad. The bridge is located near the northern edge of town near a number of cold storage warehouses and a residential neighborhood (c. 1900-1920).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span, thru-girder bridge with floor beams has reinforced-concrete substructure and cantilevered sidewalks. The sidewalk has original steel railing on the west elevation, but a chain-link fence has replaced the railing on the east elevation. The bridge has been redecked, and the inside face of the girders is protected by modern concrete barriers. The bridge is a representative example of a popular type of overpass. It is not historically or technologically significant.

Waddell, J. A. L. Bridge Engineering. New York: John Wiley, 1916.

PHYSICAL DESCRIPTION The bridge's main span is a single-leaf trunnion bascule of the overhead counterweight type designed by the Strauss Bascule Bridge Company of Chicago, Illinois. The four approach spans are encased through plate girders. Overall, the bridge is 381' long with 30' roadway.

The bascule span is constructed of two girders that span a distance of 80' from toe bearing to trunnion. The girders are tapered from approximately 12' depth at the trunnion to 6' depth at the toe. Floor beams of 15" depth frame into the girders. In addition, there are steel cross braces which act as stiffening members for the bascule span. The floor beams support steel stringers and a steel grid deck. Two 5'-wide wood-plank sidewalks with steel railing are supported by steel brackets and steel stringers on either side of the movable span. The overall width of the bascule span including sidewalks is 40'.

The counterweight is a steel frame that holds concrete block 13-1/2" x 13-1/2" x 9-1/2". According to plans, the average unit of weight of the counterweight is 148 lbs. per square foot. The counterweight is attached at the bottom by means of a laced steel channel strut and pin connection to the short arm of the bascule girders, and at the top by means of a counterweight link pin and laced steel channel arm to the top of the tower. The tower consists of two riveted laced steel channel legs and lateral bracing.

The bascule leaf is opened by a pinion gear engaging a rack of 10'8" radius on the short arm of the bascule girders. The pinion gears are operated by a electric motor. The bascule moves through a 79 degree angle from the closed to the fully open position. According to Waddell, in his well-known book entitled Bridge Engineering (1916:704), the unique system of counterweight connections in the patented Strauss system "provides for parallel movement of the counterweight at all times, and thus does not alter the ratio of lever arms nor displace the centre of gravity of the system, which is at the main trunnion of the bascule."

The movable span provides a navigational clearance of 60' with a minimum vertical clearance of 6' at mean high water. The bridge has timber-pile fenders. A two-story wood frame operator's house with asbestos siding and hipped roof stands next to the bascule span on the east side of the tower. The operator's house contains a 35 hp. General Electric Motor, an auxiliary gasoline engine, brake, clutch, and other operating machinery and controls. The operator's house rests on the concrete pier and is reached by means of a steel staircase leading down to the first story from the bridge walkway.

The approach spans consists of four concrete-encased, 74'9"-long through plate girder spans, two spans each to the north and the south of the main span. Each span consists of two girders made up of web plates and angles approximately 8' depth. Connecting the girders, which are on 34' centers, are 15 30-inch steel I beams. At the center of the roadway between the floor beams are reinforced-concrete struts and two 8" steel girders originally designed to support trolley tracks. Upon the floor beams rests a concrete slab deck.

The bridge foundations are reinforced concrete and consist of two abutments, four wing walls, and four piers.

HISTORY AND SIGNIFICANCE The Penns Neck Bascule Bridge (1925-1927) is an operating, well-preserved example of a significant bridge type that is becoming increasingly rare in New Jersey and the United States. The bridge was designed by the Strauss Bascule

Bridge Company and utilizes details found on most other patented overhead counterweight type bascules. It was erected during the flourishing period of the Strauss Company. The bridge is one of the best preserved of fewer than seven remaining Strauss bascules in the state. Historic documentation at the county engineer's office is outstanding; the bridge was probably the most ambitious bridge project ever undertaken by Salem County. It is a local landmark located on one of the primary highway routes into Salem City.

The bascule is a type of movable bridge, a special structural type combining both civil and mechanical engineering technologies. They are erected where navigation demands vertical clearance and the surrounding landscape does not permit elevated approaches. Thus, they are commonly found in low-lying coastal areas, like South Jersey.

The modern type of bascule bridge developed in the United States during the 1890s in Chicago. The most prevalent types of bascule bridges were the Scherzer and Rall rolling lift bridges, the Chicago City, and the Strauss Trunnion Bascule types. According to Waddell, more Strauss Trunnion types were built than any other. Joseph B. Strauss, the founder of the Strauss Company, was an ambitious engineer who graduated from the University of Cincinnati in 1882. Two years later he started his own engineering firm and became famous as the inventor and designer of the trunnion type bascule, and as the founder of a company to build bascule bridge located in Chicago. Strauss undertook large bridge projects all over the world including Japan, Egypt, China, South America, and Russia, but he is probably best known for his final and largest project, the Golden Gate Bridge in San Francisco completed in 1937 (Plowden 1974:248-250; Waddell 1916:700-716; Hool and Kinne 1923:1-27.)

The current bascule lift is the fifth bridge that has spanned Salem River at or near the present site since ca. 1810. In that year the citizens of Lower Penns Neck Township and Salem requested the Board of Freeholders to build a bridge just below the forks with Fenwick Creek. The bridge has since been known as Penns Neck Bridge. The first bridge was a timber structure with "a lift draw in two sections, being cut diagonally from hinge to end, so that, when opened, two right-angled triangles stood on their bases on each side of the opening" (Sparks 1927:1). In ca. 1819, the first bridge had deteriorated and a second bridge, also with a lift draw, was built. In 1843, a third bridge was constructed after the earlier bridge had again deteriorated. The draw was a pivot, or swing type bridge.

In 1884, a fourth bridge, an iron truss with two stationary spans on the Salem side of the river, a swing draw on the Penns Neck side with two channel ways of 48' each, and a short-span pony truss connecting the swing span with the Penns Neck shore, was constructed by the county. The bridge had masonry abutments and piers, except for the swing span's central pier, which was timber cribbing. In 1914 an oil barge drifted into the stationary thru truss next to the movable span and knocked it from its foundations. A steel Pratt truss was erected by the Bridgeton Construction Company in its place, and the masonry piers were encased in concrete. In 1916 the short pony truss was replaced with a steel stringer span with concrete deck (Sparks 1927:1-2).

In July 1924 the Board of Freeholders faced the proposition of reconstructing the old bridge or building a new one. Mr. John L. Vogel, consulting engineer from Manasquan, NJ, was hired to prepare a report on the condition of the bridge. He concluded that the old structure was not of sufficient width of roadway and could not be strengthened properly to take care of heavy traffic, and recommended that the most economical decision was to build a new bridge. In October 1924, the Board agreed to build a new bridge and authorized the preparation of plans and specifications for a bridge having 30' roadway, two 5' sidewalks, and a movable span of the trunnion bascule type. For a number of years the Board had been setting aside money in the county's annual budget for repair or replacement of the Penns Neck Bridge. In 1925 there had already been raised approximately $200,000 toward the project (Sparks 1927:1-5; Salem Standard and Jerseyman 1927).

James B. Sparks, the assistant county engineer, was placed in charge of the design and construction of the bridge. He had studied engineering and land surveying by correspondence and had been hired as the county's first assistant engineer in 1916. He was active in local politics and was President of the Salem Chamber of Commerce in 1927. Sparks favored the Strauss Bascule design, and had been in correspondence with the Strauss Company from at least as early as 1916 when repairs were made to the Penns Neck Bridge. It was decided that the Strauss Company would provide plans and specifications for the new movable span, and bids would be accepted for a general contractor. The county advertised the project on October 27, 1924, and opened bids on November 8. The contract was awarded to Samuel B. Campbell of Pennsville, NJ for $356,580. Campbell was one of the area's largest contractors and had built numerous bridges in the county including the Quinton Bridge, Fenwick Bridge, Upper Canal Bridge, and Courses Landing Bridge (Sparks 1927:4; Salem Standard and Jerseyman 1932; Salem Sunbeam 1964.)

Work began immediately with preparation of plans, surveying of the site, and securing of the necessary permits. Sparks stated that "the overhead type of counterweight was adopted through necessity owing to the low elevation of the surrounding territory adjacent to the bridge, making it impossible to have an underneath counterweight without the construction of an expensive watertight counterweight pit. This overhead type is not as desirable from an esthetic point of view but just as satisfactory from a mechanical point. A double leaf bascule would have presented a more uniform appearance but would not have been economical" (Sparks 1927:12). The War Department, Corps of Engineers, gave its approval of the project, and the State Highway Commission approved the plans and awarded $25,000 toward construction. Subcontractors included the Phoenix Bridge Company for the structural steel, concrete counterweight, and machinery; Donald J. McCloskey for electrical engineering; Charles S. Wright for the electrical work; and, Robert W. Hunt Company for inspection of materials at the manufacturing plants. Construction began in 1925 and was completed in December 1927. Photographs and engineering notes on the bridge erection are at the Salem County Engineer's office (Bridge Files 1925-1927).

On December 3, 1927, the Penns Neck Bridge was opened to traffic and dedicated. The day's program began with a banquet at the Johnson Hotel with numerous speeches and toasts. Morris Goodkind, the Bridge Engineer of the State Highway Department, was in attendance and stated that "the county had a bridge that all should be very proud.... few counties in the state had expended a like amount on a single bridge construction, and the county is to be congratulated that it is being financed without bond issue and will be paid for before the tax payers realize it.... Mr. Sparks was wise in the selection of this type of bridge and... the county had received a splendid piece of workmanship" (Salem Standard and Jerseyman 1927.) The banquet was followed by a parade with bands and floats, more speech making, and a ceremonial opening of the bascule. Afterward, a committee of ladies served coffee and sandwiches to the paraders from the kitchen of the H. J. Heinz plant.

The bridge has survived with few alterations. In 1932 the trolley tracks and wiring were taken up after the Pennsgrove Traction Company stopped service to Salem. At the same time, the wood block flooring of the bascule span was replaced with a steel grid deck. In 1935, and again in 1948 and 1966, repairs were made to the fender system. In 1950 the bridge was transferred to the care of the New Jersey

Department of Transportation. In 1982 the concrete piers and counterweight were rehabilitated by the state highway department (Bridge Files and Plans).

Since the construction of the Penns Neck Bridge the maritime economy of Salem has declined. At one time the city boasted a fishing fleet and a cannery, and in 1917, 83,000 tons of water-borne commerce passed along the Salem River. In 1935 the Penns Neck Bridge opened to navigation 176 times; today, the bridge opens so infrequently that no full-time tender is required, and 24 hours notice must be given (Bridge Files 1936; Heston 1924:502).

SETTING / CONTEXT The two-lane bridge spans Alloways Creek at the center of the village of Quinton (c.1800-1990). Opposite the bridge is a lumber store and a parking lot. Just upstream can be seen a dock with a number of small pleasure craft. The surrounding residential and small commercial neighborhood lacks historic integrity and has many modern intrusions.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Not Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge's main span is a center-bearing, thru-girder, bobtail swing span with an encased steel stringer with concrete parapets approach span to the south. The bridge has not opened to navigation since the late-1960s, and electrical service and operator's shanty have been removed. The swing span is one of two similar bridges in the region (0601152), and better preserved and more historically and technologically distinguished examples of the swing bridge type exist in the state.

INFORMATION

SOURCES:
Hool, George A. and W. S. Kinne. Movable and Long-Span Steel Bridges. New York: McGraw Hill, 1923.
New Jersey State Highway Department Bridge Division. Bridge Plans File No. 1708151. 8 Sheets. 1925.
Salem Standard and Jerseyman. 18 February, 4 March, and 19 August 1925.
Waddell, J. A. L. Bridge Engineering. New York: John Wiley & Sons, 1916.

PHYSICAL DESCRIPTION The main span of the two-span bridge is a 100'-long, bobtail swing bridge providing a 30' channel for river navigation. The eastern approach span is a 41'-long encased steel-stringer bridge with paneled concrete parapets. The swing span's superstructure consists of two riveted plate girders, I-beam floor beams and stringers with riveted connections, lower lateral bracing, and steel-grid deck. A concrete counterweight with supporting steel-beam framework is underneath the deck on the shorter, eastern end of the span. A 6'-wide cantilevered sidewalk extends from the south side with original pipe railing and decorative lattice. The bridge has a reinforced-concrete substructure and timber pile fenders.

The swing span is a center-bearing type. The bridge has not opened to river navigation since the mid-1960s. The operating machinery remains extant, but the operator's shanty and all electrical service and controls have been removed. An electric motor is mounted to the floor beam system by brackets at the bridge's center. The motor turned a single pinion gear against a rack of approximately 10' radius. The center bearing is mounted to the top of the center pier. The bridge was designed to open in either direction. Four balance wheels are attached to the floor-beam system and roll on a circular track above the rack. These wheels are so adjusted that they carry no load, except when the bridge is out of balance. The whole bridge turns upon a center bearing. A box-shaped system of four cross girders supports the bridge's weight upon the bearing when the bridge is in the open position. A set of six wedges, two at each end of the bridge and two at the center pier, lift the bridge in the closed position and provide it with a seating on the piers and abutments. The wedges were operated by the electric motor and a system of direct-drive line shafting and gears.

The superstructure itself has not been significantly altered. A beam guide rail has been bolted to the interior of the thru girders, and a water pipe has been attached to the north elevation. In 1960 the state highway department added the steel-grid deck, which originally had been wood block pavement.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE The center-bearing swing span over Alloways Creek at Quinton is a representative and late example of early 20th-century swing span technology. It is one of two similar bridges in the South Jersey area. The other bridge, NJ 47 over Menantico Creek in Cumberland County (0601152), is less well preserved, the stringer encasing has been removed from the approach span. The Alloways Creek bridge is not technologically innovative or noteworthy, as by 1925 both the type and the design were common technology. There are over 20 swing span bridges in New Jersey, with over half still operating.

The swing span is a type of movable bridge, a special structural type combining both civil and mechanical engineering technologies. Swing spans were one of the most prevalent types of movable bridges during the 19th and early-20th centuries. The NJ 49 over Alloways Creek bridge is a late example of movable-bridge technology employing girder superstructure, wedge end lifts, and electrification, all of which were improvements in swing span design during the period between 1890 and 1920.

A bridge has spanned Alloways Creek at Quinton since at least the late-eighteenth century. According to local lore, during the American Revolution colonists chopped away a bascule bridge at Quinton in an attempt to stay the advance of British soldiers through southern New Jersey. In 1892, the Berlin Iron Bridge Company of East Berlin, Connecticut, erected a pony-truss type swing span at the site. Plans for the 1892 bridge are in the bridge files at the New Jersey Department of Transportation. The current thru-girder type swing span replaced the 1892 bridge, which had become unsafe.

The State Highway Department designed the swing span over Alloways Creek as part of the state highway expansion and improvement campaign of the 1920s. Samuel Campbell, a contractor from Bridgeton, constructed the new bridge. Campbell was the general contractor for many bridges in Salem County including the Fenwick Bridge (1704150) and the substructure and approaches of the Penns Neck bascule (1707150) in Salem. In March 1925 the War Department, reviewing as a matter of course plans for all bridges over navigable

November 12, 2002

waters, approved the swing span's design. In August 1925 the state opened the new bridge and the local paper proclaimed "it to be one of the most attractive of its kind in South Jersey." The swing span apparently never saw much navigational use, opening fewer than 30 times per year in the 1930s. The bridge was closed to river traffic in the mid-1960s, a testimony to the declining maritime economy of South Jersey.

SETTING / CONTEXT The two-lane bridge spans Oldmans Creek about 7/10 mile east of the Delaware River. On the southeast creek bank is the original poured-concrete operator's house. The bridge no longer opens to river navigation. Nearby are numerous earthen dikes to protect farmer's fields from flooding. About 1 mile to the west on the horizon is a chemical factory.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge's main span is a vertical lift with a thru-girder deck, steel towers with portal bracing and lateral stiffening trusses, wire rope lift cables, concrete counterweights with plate girder frames, and central overhead machinery house. The three approach spans are encased steel stringers with concrete balustrades. The bridge is one of three similar Waddell-type, vertical-lift bridges on old NJ 44 in Gloucester and Salem counties. All three are eligible.

INFOR MATION

SOURCES:
New Jersey State Highway Commission, Division of Bridges, Oldmans Creek Bridge Plans, 1936.
Pulver, H. E. "Vertical Lift Bridges," in George A. Hool and W. S. Kinne, eds., Movable and Long-Span Bridges. New York: McGraw-Hill, 1923.
Waddell, J. A. Bridge Engineering. New York: John Wiley & Sons, 1916.

PHYSICAL DESCRIPTION: The two-lane bridge is a single-span movable Waddell-type vertical lift with three encased steel stringer approach spans. Its overall length is 228' with a 40' roadway. The main vertical lift span consists of a single, 92'-long toe-to-toe, 7'-deep thru girder with floor beams. The span is constructed to permit it being lifted vertically to a height of 64' clear above mean low water. At each end of the main span are steel towers approximately 96'-high. Each tower consists of two legs with horizontal and diagonal sway bracing. Between the tops of the opposite towers pass two trusses, and suspended between the trusses is the central overhead machinery house. The towers and bracing are all riveted angles, channels, and beams steel construction. Cantilevered off both sides of the main span are concrete deck sidewalks with sheet metal balustrades. The main span is no longer operable.

Power for lifting the bridge is supplied from the central overhead machinery house that contained an electric motor and a back-up gas engine. At the top of each of the four tower legs are sheaves over which pass steel-wire ropes. The ropes are attached at one end to counterweights and at the other to couplings attached to the roadway. Power was transmitted from the motor to the sheave coupling by means of direct drive line shafting and gears. The span moved up and down along a C-shaped guide on the interior of the tower legs. The machinery was equipped with electric motor brakes and clutch. The two counterweights consist of concrete blocks held within riveted steel plate frames on the exterior side of the tower legs.

The approach spans are concrete encased steel stringers with concrete balustrades and sidewalks. There are three approach spans, two to the north and one to the south of the main span, each approximately 45'-long. The bridge has a concrete substructure with cutwater piers. The fenders are timber piling. At each end of the main span are safety gates original to the bridge construction. East of the south approach is a square-plan, single-story, 2-bay, poured concrete operator's house with hipped roof.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The vertical lift bridge across Oldmans Creek is a well-preserved, albeit no longer operable, example of a historically and technologically significant bridge type. The vertical lift type represented important advances in structural steel construction, and was an alternative to bascule and swing span type movable bridges. The Oldmans Creek Bridge is one of three vertical lifts along old New Jersey Highway Route 44 in Salem and Gloucester Counties. All three bridges, built between 1935 and 1940, have been recommended as eligible because they represent an increasingly rare early 20th-century bridge type.

Vertical lift bridges are a special bridge type combining both mechanical and civil engineering technologies. The first vertical lift bridge of importance in the United States was designed by well-known bridge engineer, J. A. L. Waddell. In 1894 he oversaw the construction of the South Halsted Street Bridge over the Chicago River in Chicago, Illinois. The bridge, which had overhead trusses between the towers and sheaves at the top of each tower leg, became known as the Waddell-type vertical lift. Beginning in 1908 vertical lift bridges were built in increasing numbers, often replacing swing-span type movable bridges. According to bridge engineer H. E. Pulver (1923) the advantages of the vertical lift included simplicity of design, rigidity, reliability, ease of operation, short time of operation (usually 40-50 seconds), power economy, cost of operation, and less chance of collision with boats. The bridge type was particularly suitable to long span crossings where high navigational clearance was required.

The Oldmans Creek Bridge was built in 1936 as part of the reconstruction of NJ Highway Route 44. The firm of Ash, Howard, Needles, and Tammen of New York and Kansas City acted as consulting engineers on the New Deal public works project. The bridge was sealed to navigation in the late 1960s when South Jersey's declining maritime economy no longer made a movable span on Oldmans Creek necessary. No record of repairs or alterations to the original bridge structure could be located. Plans indicate that the bridge was built with light standards and lanterns.

The Oldmans Creek Bridge is the second youngest of the three bridges on old NJ Highway Route 44. The oldest vertical lift bridge, NJ 44

over Mantua Creek in Paulsboro (0806150), is nearly identical to the Oldmans Creek Bridge. It is still operable and has been outfitted with new operating machinery and operator's house. The youngest bridge, US 130 over Raccoon Creek (0807151) is also operable. It is of different construction and has been retrofitted with machinery and a new operator's house. As a group the bridges are neither the oldest or largest of their type in the United States, however, they are significant engineering achievements representing the application of vertical lift bridge technology to medium-span crossings.

SETTING / CONTEXT The narrow two-lane bridge spans a shallow creek along a tree-lined section of county highway. The surrounding area is rural with fields, wooded lots, and scattered residences (c. 1850-1980). The concrete abutment of an earlier bridge is just upstream. Fifty yards further upstream on the Pine Tavern-Elmer Road is a steel stringer bridge (1933) across Muddy Run.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span, T-beam bridge with reinforced-concrete substructure is a representative example of at least 17 existing T-beam bridges built by Salem County between 1917 and 1944. Beam guide rails have replaced the original pipe railings. The bridge is not historically or technologically significant.

SETTING / CONTEXT The bridge carries two lanes of eastbound US 22 over the North Branch of the Raritan River south of the early-19th century village of North Branch. It is paired with a similar 3-span arch bridge (1801154) that carries opposing traffic. The 2 are considered one resource. US 22 is a busy highway in a moderately developed suburban residential and commercial area with some older villages and farms. Next to the bridge is a municipal ball field and park and a 19th-century farmhouse.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge is a three-span reinforced concrete arch with concrete balustrades and pylons. The bridge is distinguished by its concrete pylons with numerous decorative tile mosaics. The mosaics depict sea animals, landscapes, and abstract designs. Except for the removal of lanterns, the bridge and its adjacent twin span are well preserved. Taken together the spans are two of the more elaborately ornamented and well-proportioned 1940s highway bridges in New Jersey.

INFOR MATION

SOURCES:
New Jersey Department of Transportation. Bridge Plans 1801153, 1930.
New Jersey Department of Transportation. The Development of Transportation in New Jersey, 1972.
New Jersey Department of Transportation. Straight Line Diagrams, 1988.
Fox, Robert. Interview with Mary McCahon at Trenton, NJ, 4/7/92.

PHYSICAL DESCRIPTION US 22, a median-divided 4-lane arterial route, is carried over the North Branch of the Raritan River by two skewed three-span reinforced concrete arch bridges, one carrying the eastbound lanes (1801153) and the other the westbound lanes (1801154). The elliptical arch bridges parallel each other and are approximately 48' apart. They share common continuous concrete abutments. Structurally the bridges are mirror-image twins. Both have concrete balustrades with plain hexagonal balusters and vertically-scored posts that are expressed as shallow pilasters at the abutments and piers, molded spandrel walls, and pylons above the exterior balustrade end posts. The most striking feature of the bridge is the tile and mosaic work on the balustrades and pylons that mark the approaches to the spans. The Moravian Tile Works-like mosaics depict sea creatures, landscapes, sail boats, and abstract designs. Except for the removal of original luminaries from the pylons, both bridges are well preserved. Beam guide rails have been added.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE The mirror-image pair of reinforced concrete arch bridges built in 1942 is historically distinguished as a major State Highway Department-designed bridge at a major crossing that reflects the departmental emphasis of integrated aesthetics into sound engineering solutions (criterion C). The faience tile work and mosaics in tandem with the elegant proportions of the arches to make the bridge stand apart from its contemporaries. The bridges were constructed as part of the NJ Highway Route 28 improvements. The 4-lane highway bypassed old NJ 28 (the Easton Turnpike) to the north, and was graded and constructed with the help of Works Progress Administration workers during the Depression. The New Jersey State Highway Department prepared plans for the 4-lane highway as early as 1930, but the project was completed in stages, the bridges over the North Branch of the Raritan River being some of the last work finished.

No records have been located to determine the manufacturer of the tiles and mosaics. The plans called for the tiles to be of "frost proof faience tile on plastic clay base of selected grade and equivalent to that manufactured by the Mosaic Tile Co., Zanesville, Ohio, and New York, N.Y., or the Mueller Mosaic Co., Trenton, N.J." It is not known whether either of these companies received the contract to provide the tile. The tiles and the concrete molding of the bridge show superior workmanship.

The bridges were designed by the State Highway Department bridge division headed by Morris Goodkind (1888-1968), chief bridge engineer for the state from 1925 until 1955, when he went into private practice. He oversaw the department during its period of greatest expansion. Goodkind was noted for advocating the use of concrete, both as a primary material and as encasement for protecting steel primary members, and he won several important awards over his lifetime for his bridges, including the College Bridge over the Raritan River at New Brunswick. The bridge, which carries US 1, was renamed in his honor in 1969. Aesthetics was a very important aspect of bridge design to Goodkind, and he worked with Arthur Lichtenberg, who studied architectural engineering at Pratt Institute and was the first head of the architectural section of the department. Mr. Lichtenberg retired about 1970. The collaboration resulted in the high quality designs that distinguished the bridges built on state routes between the two world wars. According to Robert Fox, a longtime coworker of Mr. Lichtenberg, it was Mr. Lichtenberg who designed the faience tile decoration. Such detailing was not used after the second world war because of its expense. Mr. Fox also stated that major bridge designs were site specific to blend with their setting. The US 22 bridges over the North branch Raritan River reflects the union of aesthetics and sound engineering that is the hallmark of the department.

Boundary Description and Justification: The pair of bridges is considered as one resource. The area between the two spans is considered as part of the resource. The boundary extends to the upstream most and downstream most fascias of the bridge. It includes both spans and the river and riverbank between them.

SETTING / CONTEXT The bridge carries 6-lanes of highway traffic across Green Brook, which forms the border between Somerset County and Union County. US 22 is a busy commercial strip, and next to the bridge is a large shopping center. The surrounding area is densely developed suburban residential and commercial.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span, encased steel stringer bridge with 2 sidewalks and median barrier has concrete balustrades, concrete substructure, and paneled fascia stringers. The bridge was constructed in 1929 as part of the NJ Highway Route 29 improvements, and widened on the northern side in 1938 with a matching encased steel stringer addition. In 1953 the highway was redesignated US 22. The bridge is a common NJ Highway Dept. bridge type, and is not historically or technologically distinguished.

SETTING / CONTEXT The bridge carries 4-lanes of US 202 over the North Branch of the Raritan River. The surrounding area is moderately developed with modern office complexes and suburban residences. The river flood plain is undeveloped and wooded.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-proportioned 3-span, reinforced-concrete arch bridge has been widened with a matching addition on the north side. The abutments and piers have Moderne detailing and paneling, as well as faience tile accents. The bridge was built as part of NJ 29, and was widened in 1959. Although representative of the arch spans produced by NJDOT in the 1930s and 1940s, this span has less integrity than others of its type in the region (1801154) and is thus not a significant example of the type.

SETTING / CONTEXT The bridge carries two lanes and shoulders of US 206 over Dukes Brook south of Somerville. The west fascia of the bridge is part of the Duke estate, which is surrounded by a stone wall that passes across the bridge on the upstream side. The estate was developed 1893-1925 by tobacco magnate James B. Duke as his gentleman's farm. The some 1,250-acre estate has been found eligible by the SHPO in a 9/16/83 finding. US 206 r-o-w is the east boundary, and most of the bridge is not included.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. West elevation element of the Duke Estate. Contributing.

CONSULT DOCUMENTS SHPO Finding 09/16/83, Letter 03/12/01. DOE 02/12/85.

SUMMARY The bridge is a skewed, reinforced-concrete deck arch. The east side is finished with a plain concrete spandrel wall and a railing with concrete posts that once held pipe rails. The west side has a stone fascia finished in the same style as the rubble coursed stone wall that encloses the Duke estate. It was finished to conform to Duke's architectural scheme. While the structure is not individually eligible for listing in the National Register of Historic Places , the west elevation (only) of the bridge, because of its historical and physical association, is a contributing element of the National Register listed Duke Estate under Criteria A and C.

INFOR MATION

SOURCES:
James B. Duke Estate, National Register Nomination. Office of New Jersey Heritage. 1987.
Jenkins, John Wilbur. James B. Duke, Master Builder. New York: George H. Doran Co., 1927.
New Jersey Department of Transportation. Bridge Plans, 1911.

PHYSICAL DESCRIPTION: The bridge is a single-span, skewed, reinforced concrete elliptical deck arch. The east side of the bridge is finished with a plain concrete spandrel walls with concrete posts that once held a pipe railing. The west side of the bridge is within the Duke's Farm historic district, and it is finished with the same rubble coursed masonry used throughout the estate. It is the same as the stone wall that defines the limits of the estate along US 206. The wall is separated from the roadway by a grass berm. The wall and west spandrel wall are constructed of undressed weathered rocks of various sizes, shapes, and coloration's. Rounded flat buttresses mark the limits of the span and add relief to the structure. The wall is approximately 2 ½' thick and stands over 6' high. The west side of the bridge is not visible from the right-of-way nor is it accessible from the right-of-way.

The eastern extrados shows numerous concrete patches and is bowing outward. A beam guide rail has been added. The estate wall is in excellent condition.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The western side of the bridge was designed and finished to conform with the overall architectural scheme of James B. Duke's estate, Duke's Farm. The estate is considered National Register eligible for its association with tobacco magnate Duke, and for its architectural significance as an outstanding example of a Gilded Age country estate built in a romanticized style. The landscaping, including the boundary walls, bridges, and series of drives are significant contributing elements to the estate's historic integrity. The "boulder-style" boundary wall along the west side of US 206 serves as the boundary of the historic district, as specified in the 1987 draft nomination, may have been built in direct response to the county's improvement of the roadway that eventually became a state highway and then US 206. Part of that improvement was the building of a bridge over Duke's Brook.

Tobacco magnate James B. Duke had purchased the Hillsborough Township land in 1893 and was developing the it according to his ideas of a grand gentleman's farm. In 1903 he hired landscape architects Buckenham and Miller of New York City to carry out a romantic landscaping plan that included numerous lakes, pathways, bridges, fountains, well-houses, and buildings. Part of the plan included surrounding the estate with a rusticated stone wall, an idea that may have been given impetus in 1911 when the county announced its plans to build the highway and bridge along the eastern boundary. Duke requested that the county allow his architects a say in the bridge design so that it conformed with his overall scheme. The wall, which was incorporated into the west side of the bridge, was an example of the boulder style, which appealed to the Victorian-period aesthetic sense of the romantic in the natural environment. The wall was constructed by two teams of Italian masons from Long Island, Curcio Brothers and Barone and Darienco. The bolder style finish is limited to just that portion of the bridge that is visible from within the estate, not the other side. Thus Duke's contribution and involvement with the span appears to have been the finish on his property, not the overall appearance of the bridge.

The 1911 bridge is a reinforced concrete deck of the type and style that was first used by the county in 1910. It is one of over fifteen built by the county in the 1910s. The span is not technologically or historically distinguished save for the west facade which is part of the proposed National Register historic district.

Boundary Description and Justification: The west elevation of the bridge is contiguous with the stone wall that marks the east boundary of the Duke's Farm Historic District, a proposed historic district. The estate was determined eligible by the SHPO in 1983, and a draft nomination with specific boundaries was prepared in 1987, but no determination by the National Park Service has been rendered. The significant portion of the bridge is limited to the stone-faced west elevation. it does not extend to the portion of the structure that is part of the r-o-w of US 206.

SETTING / CONTEXT The bridge carries 4-lanes of US 206 over the Raritan River south of Somerville. South of the bridge is near the public entrance to the Duke Estate gardens. The entire estate has been determined eligible for the National Register by the NPS (9/16/83). The bridge is not on the estate, but it is contiguous to the estate. The area along the river is wooded.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-span, open spandrel, barrel arch bridge is one of over 10 well-detailed and handsomely proportioned example of its type built by the State Highway Dept. in the late-1920s and 1930s. It is finished with a concrete balustrades with exedrae, and pylons that originally carried classically-inspired luminaries (removed). The bridge is well preserved and is representative of the handsome spans the state designed for major crossings on its rapidly expanding road network.

INFORMATION

Bibliography:
Condit, Carl W. American Building Art. 1961.
Proceedings of the American Society of Civil Engineers. August 1930.
Hess, Jeffrey A. and Frame, Robert M. Wisconsin Stone arch and Concrete Arch Bridges. 1986.
Plowden, David Bridges: The Spans of North America. 1974.

Physical Description: The well-proportioned 4-span open-spandrel reinforced concrete arch bridge is 382' long. The graceful elliptical arches spring from well-detailed bullnose concrete piers, and the spans are articulated by paneled posts that extend from the piers into the paneled posts of the concrete balustrades that frame the sidewalks. The spandrels over the elliptical main span arches are filled with full-width columns. Original standards and luminaries have been replaced with modern aluminum posts and lights. Guide rails have been added at the curblines. With the exception of the modern lights, the bridge remains as it was originally designed.

Historical and Technological Significance: The well-proportioned and well-detailed open-spandrel arch bridge built in 1929-1930 is significant because it represents the quality designs that Morris Goodkind(1869-1968) produced throughout his career as the State Bridge Engineer for the New Jersey State Highway Department. The US 206 bridge is one of the earliest of the approximately 8 open-spandrel arch bridges in New Jersey, a bridge type that defines the highest level of refinement in reinforced concrete arch technology. The well-preserved bridge represents Goodkind's emphasis in the New Jersey State Highway Department Bridge Division to create aesthetically pleasing concrete structures prior to World War II. The moldable qualities of the material were used to create an architectural masterpiece at the same time that its structural qualities were used to efficiently carry a major highway across a wide river. The reinforced concrete arch was capable of relatively long spans while providing graceful and dynamic forms (Criterion C).

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type. A massive structure, the open spandrel arches span 233 feet with virtually no steel reinforcement in the two ribs. In the first two decades of the 20th century, railroads began using reinforced concrete to construct large viaducts across rivers and valleys to eliminate steep grade changes. The length and number of spans increased to create massive structures that dominated the landscape. The Tunkhannock Viaduct (completed 1915 and designed by A. Burton Cohen (1883-1956) of the Delaware Lackawanna & Western RR in Nicholson, Pennsylvania remains one of the greatest bridges in America. It is a ten-span open spandrel reinforced concrete arch, 2375 feet in total length, each span 180 feet in clear span, and rising 240 feet above the creek bed in the valley floor.

The US 206 bridge was completed 14 years later in 1929, but is comparable in beauty and technological significance.

Morris Goodkind, designer of the bridge, was a graduate of Columbia University. He worked for the New York City Public Service Commission in the development of the subway system before working on bridge designs for engineering firms and Mercer County, NJ. In 1922 he joined the New Jersey Highway Department, and became the Chief Bridge Engineer in 1925, a post he held through 1955 when he retired to private practice.

The 1920s and 1930s were a time of great expansion of the state's highway system required many bridges to be built. Goodkind emphasized the need for aesthetically pleasing as well as structurally sound bridges. He brought in Arthur Lichtenberg to develop an architectural section in the Bridge Department. Many of the grade elimination bridges of the 1930s and 1940s in congested areas were detailed with Moderne and Deco pilasters and entablature due to the influence of Goodkind and Lichtenberg. The same structures had encased stringers, the most common type built during Goodkind's term. He emphasized the encasement for protection of the steel from the elements, a valid assertion considering the number and condition of such structures remaining in New Jersey.

While working for the state, he served as a consultant on bridge construction for the War Department. Upon his retirement as Chief Bridge Engineer, Goodkind became a consultant with the firm of Goodkind and O'Dea in Manhattan. He was internationally known and respected for his bridge engineering. He had been active in local and national engineering societies, and won several awards for the

designs of bridges. Goodkind was awarded the Phoebe Hobson Fowler Architectural Award by the American Society of Civil Engineers for the design of the US 1 bridge in New Brunswick (1203150).

Boundary Description and Justification: The bridge is evaluated as individually significant. Independent of its historical and technological significance is the fact that it is situated on a road (US 206) that forms the east boundary of the D.O.E. Duke's Farm Historic District. The 1987 draft nomination uses the middle of river as the boundary. Thus the bridge, located at a northeast corner of the district, is partially within the district. The property bordering the southwest quadrant of the bridge has been determined to be historic, but the property bordering the others has not. The history and significance of the bridge is not related to the history and significance of Duke's Farm.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The rivet-connected skewed 3-span Howe pony truss with counters overpass on ashlar abutments and 1914 steel bents is an example of an uncommon truss type. It is an unconventional design with small spacer panels added to each truss to compensate for the skew. The floor beams are perpendicular to the road. Even though all but a few of the built-up floor beams and the flooring system have been replaced, the 1889 bridge survives as a good example and unusual example of its type.

INFOR MATION

Bibliography:
Conrail Records.
NJDOT Plan File: 6118 (45.95).
Gibb, Hugh. "Brotherly Love - Philadelphia Style," Bulletin of the National Railway Historical Society, 39, No. 6, 1974, pp. 21-43.

Physical Description: The skewed three-span rivet-connected Howe pony truss bridge is supported on ashlar abutments and metal bents composed of toe-out angles. The lateral bracing on the bents was added in 1914. A Howe truss works on the opposite principle of the more common Pratt truss. The verticals are in tension, and the diagonals and counters are the compression members. The chords, verticals, and diagonals are composed of toe-out angles while the counters are dimensioned plate. The original floor beams, which have been replaced at least twice, were built up. The floor beams are perpendicular to the roadway, not the abutments. The most unusual design detail of the trusses is the use of a small panel at either end of each truss which allowed for equal sizing of each pair of skewed trusses. The bridge has been strengthened with welded knee braces on the inside of the trusses and plate welded to the top chord. The stringers and flooring were originally wood, but they have been replaced with steel stringers and an asphalt wearing surface. A modern beam guard rail protects the inner face of the trusses.

Historical and Technological Significance: The Howe pony truss bridge was designed by the Philadelphia & Reading Railroad Chief Engineer's Office in 1889. In addition to being one of the few documented example of a Howe pony truss bridge in the state, it ranks as the oldest railroad-related span in Somerset County. Why a Howe truss was used is not documented, but it may relate to the decision to reuse the existing substructure which divided the bridge into three spans. The use of the small panels at the end of each truss in order keep each pair of trusses the same length is also an unusual design detail. In 1914 the bracing between the bent posts was added as were the concrete piers, and in 1982 most of the floor beams and stringers were replaced. Despite its over 100 years of active service, the bridge is extremely well preserved and ranks as one of the distinctive pony truss spans in the state.

The bridge was constructed for the Philadelphia and Reading Railroad (Reading) at Skillman, site of the state's epileptic village. A non-extant station was located to the southwest of the bridge. The rail right-of-way was chartered in 1870 and built as the Delaware & Bound Brook Railroad by the Central Railroad of New Jersey in 1873-1875 as an alternative double-track route between New York and Philadelphia. The line was acquired by the Reading Railroad, and was used for both freight and passenger service until the 1970s when the line went bankrupt. The right-of-way passed to Conrail which found it useful for freight service displaced from Amtrak's Northeast Corridor which is the old Camden & Amboy (Pennsylvania Railroad after 1873) route. The Skillman Road overpass is also one of the oldest grade crossing elimination bridges in the region. This is at least the second bridge at the crossing.

Boundary Description and Justification: The bridge is evaluated as individually distinguished for its technological significance. It is adjacent to the campus of the State's Skillman Training School for Boys, but it is not near historic buildings associated with the early history of that facility. The boundary is limited to the substructure and superstructure of the bridge itself.

PHYSICAL DESCRIPTION: The single-span, 8-panel Warren with verticals thru truss bridge is 116'-5" long from end bearing to bearing and 28'-wide from truss center to center. It is of riveted construction and is in a good state of preservation with only minor alterations and deterioration. The design of the bridge reflects the 20th century advance of truss designs to address secondary stresses. The bridge carries a 2-lane residential street over 6 active tracks of Conrail's main freight line known as the New York Branch. A cantilevered sidewalk with lattice railing extends from the southern truss elevation.

The bridge members consist of the following steel elements: the upper chords and inclined end posts are channels with cover plates and lacing; the verticals, which pick up floor beams, and diagonals are laced angles; the upper laterals are laced angles with bracing, except for the portals which have lattice bracing; the stringers are I-beams with concrete jack arches and encased (some has failed) tie rods. The concrete abutments and wing walls are scored and inscribed with the Reading Railroad diamond logo and the date 1918. The high banked approaches have concrete parapets.

The bridge is in good condition with some spalling and deterioration of the concrete encasing, jack arches, and abutments. Some of the upper chord and lower chord riveted connections have been repaired with bolts. Concrete has been poured in the gap formed between the diagonals and the gusset plate connections at the lower chord.

Historical and Technological Significance: The well-preserved riveted Warren with verticals thru truss bridge is the only example of its type in the county. It is a type associated with the railroads, and while not uncommon in the state (there are five in Union County built between 1907 and 1926 and several in Hudson County the were also built by the CNJ), this is one of the few Warren thru truss highway bridges in the middle portion of the state making. The bridge type was favored by the railroad where a long span with reasonably high load capacity was needed. The bridge is historically important to the development of Manville, a company town started in 1913. It connected the central downtown commercial and industrial area with residential development on the east side of the railroad tracks (criteria A, C).

The railroad right-of-way spanned by the bridge was originally developed in the mid-1870s by the Reading Railroad as its Delaware and Bound Brook Line. Completed in 1875, the line was begun to provide an alternative route between New York and Philadelphia to the Pennsylvania Railroad's acquisition of the old Camden and Amboy right-of-way. The Reading Railroad route left the Central New Jersey Railroad's main line at Bound Brook and headed south across the Raritan River to Manville and on to Philadelphia. In 1976, Conrail acquired the bankrupt Reading Railroad, and has continued to use the route for freight trains.

In 1913, the Johns-Manville Corporation established its largest factory in the company town of Manville. By 1930, the 282 acre plant employed over 1,700 and produced a wide array of asbestos products including textiles, packing, brake linings, and shingles. Prior to the construction of Johns-Manville, a private farm bridge had provided an overhead crossing of the Reading Railroad at, or near, the location of Bridge Street. With the establishment of the town, it was proposed to make the private road public, and the Reading Railroad made plans to improve the crossing. Initially, a thru girder bridge was proposed, but this was set aside for an alternative thru truss design. Plans for the concrete substructure were prepared by the Philadelphia and Reading RR, and the Phoenix Bridge Co. of Phoenixville, PA fabricated the superstructure. The Phoenix Bridge Co. was the sister company of the Phoenix Steel Co., and one of the nation's largest, oldest, and most prestigious bridge builders, specializing in the manufacture of steel structural components and the erection of bridges of many types. In 1918 bridge construction was completed.

Boundary Description and Justification: Although the bridge is located in Manville, a corporate town with historical significance, the area adjacent to the span does not possess the integrity necessary to be evaluated as a potential historic district. Thus, the bridge is

SETTING / CONTEXT The single-lane bridge spans H-Conrail (former Lehigh Valley Line) west of Neshanic Station. The bridge is closed to traffic, and was once used to connect farmer's fields on either side of the track. The surrounding area is rural with scattered residential development. The bridge is similar to the 1901 pony truss section of 2151161 in Warren County, also built for the Lehigh Valley RR over a farm crossing. The Warren County example is better preserved.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The timber-decked bridge has a 5-panel, riveted Warren pony truss main span and two timber-stringer approach spans. The main span rests on timber-pile bents and the approach spans on timber pile abutments. The main span has welded repairs to the lower chord, and has been lengthened by one panel by the riveted addition of uneven sized angles and channels. Repair and construction records for the bridge have not been located. The bridge is not historically or technologically distinguished.

SETTING / CONTEXT The one-lane bridge is located on an abandoned road over the abandoned right-of-way of the former South Branch of the Central Railroad of New Jersey. The surrounding area is wooded, and the old road and bridge serve as a pedestrian way. The active Conrail freight line on the Lehigh Valley line is immediately southeast of the bridge. A stringer bridge carries the abandoned road over that line. The thru truss bridge is only seasonally visible from Mill Lane.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed Pratt thru truss bridge is fabricated with the patented Phoenix columns for the top chord, inclined end posts, verticals, and struts. Despite its deteriorated condition, the bridge, on ashlar abutments that date to 1869, has not lost its integrity. It is the only extant Phoenix column span in the county, which is known to have had many. The Mill Lane bridge is thus the sole survivor of the earliest type of metal truss bridge built in Somerset County. It is technologically notable.

INFOR MATION

Bibliography:
Conrail. Bridge File 241-2.
Waddell, J.A.L. Bridge Engineering. New York: John Wiley & Sons, Inc., 1925.
Hagley Museum & Library. Phoenix Bridge Co. Records: Clarke Reeves & Co. 1874-1884, Order Books (boxes 363-367).

Physical Description: The 10-degree skew, 5-panel, pin-connected, half hip Pratt thru truss bridge is composed of wrought iron Phoenix-sections for the compression members. The top chord, inclined end posts, portal struts, and verticals are the patented built-up Phoenix columns. Phoenix columns are made up of four rolled wrought segmental sections with flanges that are then riveted together. The individual built-up column sections are then joined by patented cast iron connecting pieces and feet or bearings also produced by the Phoenix Iron Company. The diagonals and full-length floor beam hangers are rectangular rods with loop forged eyes. The floor beams are rolled I section and are not original to the bridge, although they are attached by means of the traditional floor beam suspenders at the lower panel point pin. Despite its deteriorating condition, the single-lane bridge appears to be capable of supporting load, although the high ashlar abutment is failing. The large modern rolled I-section welded to the bottom flange of the floor beams was the first step in an uncompleted attempt to jack up the bridge.

Historical and Technological Significance: The 1879 bridge built by Clarke, Reeves & Co. for the Hibernia Mine Railroad is historically and technologically significant as an early and documented example of rail-carrying bridge built with the patented Phoenix section (criterion C). The Phoenix section, patented in 1862 by Samuel Reeves, President of the Phoenix Iron Company, was one of the most significant developments in the advancement of metal truss bridges in the 1870s. Originally applied to buildings, the company recognized the value of its use in bridges about 1868. The section was also used in early elevated street railway lines in New York City and vicinity. In 1872 Clarke, Reeves & Company was formed to handle the bridge building side of the business, and Clarke, Reeves & Company concentrated primarily on railroad rather than highway bridges. The railroads were by far the largest user of metal truss spans and viaducts through the 1870s and early 1880s. Because railroad bridges with Phoenix sections represent first-generation railroad bridge technology, and thus an era when rolling stock and loads were not what they would become in the 1890s and 1900s, few railroad Phoenix-column bridges survive. They were replaced by stiffer, stronger bridges. The history of this span is recorded in the Clarke, Reeves & Company order books preserved at the Hagley Museum and Library. With the exception of the removal of the original floor system, with its stringers and rail chairs related to its original railroad use, the span is complete, and it illustrates that overall there was no difference between some Phoenix-section railroad and the highway bridges.

The skewed through truss bridge was moved to this location by 1894, and it was installed as a grade crossing elimination by the Central Railroad of New Jersey on its South Branch. Railroad records indicate that "this bridge was transferred from the Hibernia (Mine) Railroad," a short line chartered in 1863 and operated by the CNJ. What is meant by "transferred" is not known, but it is assumed to mean moved. The span is the oldest metal truss bridge in the county and one of the oldest thru truss spans in the entire state. It is the second oldest of the eleven surviving bridges with Phoenix columns in the state and the only one built as a railroad bridge. It is the only one that was built by Clarke, Reeves & Company, the successor of the Phoenix Bridge Company (organized in 1884).

Boundary Description and Justification: The bridge is evaluated to be individually significant. While the setting is not devoid of history, it the technological and historical importance of the bridge that sets it apart. The boundary is limited to the superstructure. The substructure is too deteriorated to possess the integrity of original design needed to be evaluated as significant. The railroad right-of-way that the span crosses has been abandoned. It is overgrown.

DESIGNER/PATENT **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a single-lane over a single track of New Jersey Transit's Raritan Valley Line, formerly the Central New Jersey Railroad. The right-of-way was developed in the late 1840's by the Somerville and Easton Railroad. West of the bridge is the village of North Branch Station, which developed around the railroad in the mid-19th century. The surrounding area is residential with early homes, most of which have been altered.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS NJT HBS 3/12/91. SHPO Letter 6/30/95.

SUMMARY The bridge has been rated not eligible by the NJT Historic Bridge Survey due to the undistinguished nature of the timber stringer superstructure which was built in 1949 when the vertical clearance was raised. What is of technological merit are two pairs of well-detailed cast iron bents composed of hexagonal columns and cross bracing. They appear to be monolithic castings. Although the bridge itself is insignificant, the bents are exceptionally unusual and significant structural elements.

INFOR MATION

Bibliography:
DeLeuw, Cather, and Company. New Jersey Transit Historic Bridge Survey, 1991.
New Jersey Department of Transportation. Bridge Plans, 1949.

Physical Description: The single-lane 81'-long bridge is three span resting on stone abutments and impressive monolithic cast-iron column bents on ashlar plinths. The center span of the superstructure, placed in 1949 has rolled steel I beam fascia stringers and interior wood stringers. Two rolled section floor beams are hung from the fascia stringers. The shorter end spans are exclusively wood stringers. The superstructure has been raised from its original elevation and the stone abutments and pier bases have concrete caps. The bridge has a timber deck, timber curbing, and wood railings.

The handsome cast-iron column bents consist of two sets of paired columns with lateral and diagonal cross bracing. The columns are octagonal in cross section and are tapered and finished with pedestals and capitals. The lateral and diagonal bracing are x-shaped in cross section, except for the top and bottom laterals which are t-shaped. The bents appear to be monolithic, one-piece castings. The number "10" is cast in the eastern piers, and the number "12" is cast in the western piers.

Historical and Technological Significance: Although the bridge has been altered by the 1949 rebuilding of the superstructure, the two cast-iron columns bents are exceptionally significant examples of a very rare type of bridge structural element. According to Central Railroad of New Jersey records, the overpass bridge was initially constructed in 1886, and the superstructure was raised in 149 with the original bents remaining. The railroad right-of-way was originally developed in 1848 by the Somerville and Easton Railroad and later taken over by the Central Railroad of New Jersey. The cast-iron bents appear to be monolithic castings, and they are highly crafted. No other bents of this type have been identified to date. Much of the early success and eventual general acceptance of metal bridges and related structural elements is directly attributable to the skill of foundry men. These bents stand as a record of their knowledge and ability. Cast iron came into increasing use as a structural element in the early-19th century but was replaced with other materials such as wrought-iron, steel, and concrete by the end of the century.

The NJT Bridge Survey incorrectly identified the piers as "Phoenix Columns," which were always segmental, riveted, wrought-iron structural elements patented and manufactured by the Phoenix Bridge Company of Phoenixville, Pennsylvania. In the 1880s the Phoenix Bridge Company produced many other types of wrought-iron, cast-iron and steel structural elements. The NJT Bridge Survey recommends a status of not eligible for the bridge; because of the rarity of the cast-iron bents, A. G. Lichtenstein recommends a status of eligible.

Boundary Description and Justification: The boundary is limited to the bents. The other portions of the bridge are not significant.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 7-panel pin-connected half hip Pratt thru truss bridge is not only one of the most complete examples of the popular late-19th century bridge type in the region, but it is a rare example of the New York City fabricator Milliken Bros. that operated from 1891 until 1907 when the business failed. Few of their bridges have been documented. The design itself appears to be undistinguished from the host of other Pratt trusses of the era, but the pristine condition of the bridge is remarkable.

INFOR MATION

Bibliography:
The National Cyclopaedia. pp. 110-111.

Physical Description: The 7-panel pin-connected half hip Pratt thru truss is supported on ashlar abutments. Composed of standardized rolled sections, the bridge has a built-up box member for the top chord and inclined ends posts while the verticals are toe-out angles joined by lacing. The original built-up floor beams are connected to the verticals by U-shaped hangers while the endmost floor beams are carried on full-length hangers, an arrangement mandated by the half hip panel. The latticed portal brace carries the makers plaque. The only apparent alteration to the original design is the replacement of the original railing with modern beam guard rails. It is not known if the bridge is composed of steel and/or iron members. The bridge is extremely well preserved.

Technological and Historical Significance: The Pratt truss was the most common late-19th century bridge type, but few examples in the region are as complete as the Higginsville Road span. It survives in basically unaltered condition and is thus an important example of 19th-century technology and construction techniques. The bridge works in tandem with the 1893 Pratt thru truss (18A0605) fabricated by the Wrought Iron Bridge Company of Canton, Ohio. That span is immediately north, and the two share a common large earth-filled abutment.

The bridge was designed and fabricated by the Milliken Brothers of Brooklyn, New York (1887-1907). There are few documented examples of their work which increases the historical importance of the Higginsville Road span. Milliken Brothers was established in 1887 by brothers Foster and Edward Milliken as the successor to their father's Brooklyn company, Milliken, Smith & Co., agent for the Phoenix Iron Works. In addition to representing the Phoenix Iron Works, the brothers took on structural iron and steel work for buildings, and in 1893, they dropped their association with the Phoenixville company in order to concentrate on fabricating and erecting their own design. Foster Milliken was a structural engineer trained at Columbia University. The company flourished primarily on its structural steel and building operations with branch offices located all over the world. Because of its phenomenal growth, the brothers moved their operation from Brooklyn to a 175-acre plant complete with an open-hearth steel mill on Staten Island in 1903-06. The expansion proved to costly and ambitious, and the firm failed in 1907. Edward Milliken died in 1906, and Foster went on to work for the construction firm of Charles T. Wills.

Milliken Bros. is representative of the many small designers/fabricators who dominated 19th-century bridge construction. They obviously learned the trade serving as representatives for another company, and then went off on their own. The pattern is not unusual. Their corporate history is a significant contributor to the understanding of how early metal truss bridges were designed, marketed, and built.

Boundary Description and Justification: This span and the adjacent span (18A0605) are considered as one 2-span resource that is individually distinguished. The boundary is limited to the superstructure and substructure of the 2-span bridge, although the bucolic character of the setting does enhance the context.

SETTING / CONTEXT The southernmost of the pair of similar early bridges, this span carries a narrow country road over flood plain and auxiliary channel of the river. It enjoys an unspoiled picturesque rural setting just east of an equally pristine crossroads settlement that sprang up around a water-powered mill (Higgins Mill). The surrounding land use is predominantly agricultural. The two bridges (18A0601) share a common earthen abutment, and they are on the county line.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 7-panel pin-connected half hip Pratt thru truss bridge is one of the most complete examples of its type in Somerset County. It is supported on ashlar abutments. The verticals are composed of laced channels while the top chord and end posts are built-up box members. The most distinctive construction detail is the 4-prong basket loop on the bottom of the floor beam hangers for making the connection at the pin. The bridge is eligible because of its age and integrity of setting and design.

INFOR MATION

Wrought Iron Bridge Company. Illustrated Pamphlet of Wrought Iron Bridges Built By Wrought Iron Bridge Company, Canton, Ohio. Canton, OH: Wrought Iron Bridge Co., 1885.

PHYSICAL DESCRIPTION: The 7-panel pin-connected half hip Pratt thru truss bridge carries a single lane roadway over the flood plain and auxiliary channel of the South Branch of the Raritan River. Composed of rolled sections, the top chords and end posts consist of a built-up box member, and the lower chords are paired eye bars. The verticals are toe-in channels with lacing, except for the hip vertical which is a bar. The diagonals are paired bars and the counters single bars. The I-beam floor beams are connected to the verticals by U-shaped hangers. One of the most distinctive features of the bridge is the 4-prong basket loop on the bottom of the hip verticals for making the connection to the pin. The upper struts are I-beams, and the upper laterals are rods with turnbuckles. The portal bracing, which is composed of angles, carries a makers plaque. The bridge shows few signs of alterations except for the replacement of some riveted connections with bolts along the lower chord, and the replacement of the original railing with a beam guide rail. Bridge cards from the Hunterdon County engineer's office indicate no major repairs between 1940 and 1960 except for the routine replacement of the deck. It is not known whether the bridge is composed of steel and/or iron members. The bridge is exceptionally well preserved.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Pratt truss was the most common late-19th century truss bridge type, but few examples in the region are as complete as the Higginsville Road span. It survives in basically unaltered condition and is thus an important example of 19th-century technology and construction techniques. The bridge works in tandem with the 1890 Pratt thru truss fabricated by Milliken Brothers of New York City. That span (18A0601) is immediately northeast, and the two share a common large earth-filled abutment.

The bridge was designed and fabricated by the Wrought Iron Bridge Company of Canton, Ohio. Organized in 1864 by David Hammond, the company was one of the first wrought iron truss manufacturers, and continued in existence for 36 years before being absorbed by the giant American Bridge Company in 1900. The company claimed in its promotional literature to have constructed trusses in 30 states, mostly east of the Mississippi River. In Canton, the fabricator had shops for the drafting, laying out, shearing, drilling, punching, and riveting of truss members, but did not roll its own iron or steel. The Wrought Iron Bridge Company was recognized as one of the most significant regional manufacturers of iron and steel trusses because of its workmanship and prolificacy. Unlike many of its competitors, the Wrought Iron Bridge Company did not specialize in one truss type, but constructed a wide diversity of small and large, inexpensive and expensive truss types, depending upon local preferences. According to the company's 1885 trade catalogue, at least 10 other Wrought Iron Bridge Company trusses were built in New Jersey prior to 1885, six in Middlesex County, three in Mercer County, and one in Union County. One other Wrought Iron Bridge Co. bridge is known to survive in Somerset County, the well-preserved Nevius Street Bridge (1886), a two-span double-intersecting Pratt thru truss across the Raritan River in the town of Raritan.

The Wrought Iron Bridge Co. was one of the most successful of the many small designers/fabricators who dominated 19th-century bridge construction. The Higginsville Road Bridge is an important example of their craftsmanship, as well as a locally significant example of a bridge type that was once common in Somerset County.

Boundary Description and Justification: This span and the adjacent span (18A0601) are considered as one 2-span resource that is individually distinguished. The boundary is limited to the superstructure and substructure of the 2-span bridge, although the bucolic character of the setting does enhance the context.

CONSULT STATUS Bridge was Individually Eligible. Listed. Early Stone Arch Bridges of Somerset County Multiple Property Listing. 02/17/1994.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span bridge (c.1800) has two masonry arch spans and one metal stringer span. The stringers were added after a flood in 1892 washed out a span. A beam guide rail has been added. The Rock Brook Bridge is the only surviving example of an 19th-century combination span in the county, and it is significant for its historical and technological associations. It is part of a Multiple Property Documentation Form National Register nomination for early stone arch bridges in the county.

SETTING / CONTEXT The bridge is one of two single-lane thru truss bridges that carry a country road over the river. The setting is sparsely developed rural with fields and pastures and some 19th- and 20th-century residential development. The two bridges share a common earth-filled masonry pier. Immediately south of the pair of trusses is a third span, a concrete arch (18B0510), constructed in 1916.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed single-span Pratt thru truss has masonry abutments. Built in 1902, the bridge and its companion span (18B0512) are the youngest of 4 surviving Pratt thru truss highway bridges built in the county between 1885 and 1902. John W. Scott was a local bridge builder from Flemington, and Joshua Doughty, Jr. was Somerset's first county engineer. The upper portion of the bridge has been modified, but it is significant as part of the 2-span crossing.

Physical Description: The skewed, 101'-long, single-span, pin-connected, five-panel half-hip Pratt thru truss bridge, one of a pair of nearly identical spans that share a common large ashlar mid-channel pier, carries a single-lane road over the main channel of the South Branch of the Raritan River. Comprised of rolled sections, the bridge has built-up box member top chords and end posts. The lower chords are paired eye bars. The verticals are angles with lacing, except for the hip verticals which are paired rods. The diagonals are paired eye bars, and the counters are single rods. The portal struts and bracing are angles with decorative lattice and builders plaques. The top struts are back-to-back angles with steel rod lateral bracing. The I-beam floor beams are supported from the lower chord panel points by U-shaped hangers. The bridge abutments, wing walls, and pier are roughly-coursed red sandstone masonry, probably quarried locally.

A number of repairs have been made to the superstructure. In 1980 the county removed the original riveted cover plates of the inclined end posts and upper chords and replaced them with welded cover plates. The lattice verticals at the three middle panel points were cut and welded connecting plates added. In addition, the upper lateral struts and top lateral bracing were removed and replaced in an inverted position. The portal bracing, struts and lattice were also removed and rebuilt with new welded connections to the end posts. Other alterations and damages to the truss include a broken vertical with a welded connecting patch; a broken counter with a welded connecting patch; a snapped lower lateral brace; the removal of the original railing and the addition of modern steel guard rail; and rebuilding of the masonry abutment with a reinforced-concrete seat underneath the northeast truss shoe.

Historical and Technological Significance: The Woodfern Road Bridge across the South Branch of the Raritan River is technologically and historically significant as one of a pair of pin-connected thru truss bridges that represent bridge-building technologically from the local perspective at the turn of the century (criterion C). Erected in 1902, the Pratt thru truss with its nearly identical companion truss to the south (18B0512) are the youngest of 4 surviving Pratt thru-truss highway bridges built in Somerset County between 1885 and 1902, and the 9th youngest of 10 surviving thru trusses of all types. The Woodfern Road bridges retain integrity of design and has been in continuous use at the present site since the time of its construction. In the last decades of the 19th century, the Pratt truss type was widely used, and it played a prominent part in the advance of a reliable network of overland transportation. It was well regarded by engineers for its simplicity of design and easily determined structural action, and by the 20th century, the truss type had gained almost universal acceptance for both railroad and highway spans. The Woodfern Road bridges were erected by John W. Scott, a small bridge manufacturer from Flemington.

A bridge has spanned the South Branch of the Raritan River at the site since at least the mid-19th century. A 1860 map shows the bridge, and the minute books of the Board of Freeholders record repairs to the bridge as early as the 1880s. The proximity of the Old York Road, Somerset's main east-west road from the 17th to the 19th century, and Neshanic Station, established by the South Branch of the Central Railroad of New Jersey in the 1870s, made the crossing an important link in the rural transportation network.

The two trusses at Woodfern Road Bridge were built under two separate contracts by the same builder, John W. Scott. The southernmost truss (18B0512) was completed first in April 1902. Two weeks after the completion of the first truss span, the Freeholders decided to build a second to replace a bridge at the site of the existing northern skewed truss. They voted to build a 100' long span and quickly solicited bids. Bidders for the second truss included Scott, the Dover Boiler Works (Morris County), the Frank R. Long Company (Bergen County), the Berlin Construction Company (Connecticut), the William Kirk Company, and the American Bridge Company. The bids were closely spaced, but Scott received the contract because "his plans submitted were for a heavier bridge than the plans of the lower bidders." The price was $2400. The second truss was finished and accepted in September 1902. Both spans are believed to have replace wood truss

covered bridges.

J.W. Scott was a bridge fabricator who resided in Flemington (Hunterdon County). In 1899 he appears as a bidder on at least one other bridge project in Somerset County, but he did not receive the contract. Two nearly identical idiosyncratic pony trusses were erected by Scott in Hunterdon County 1900-1903 (100D390, 100D388). Scott appears to be typical of many small bridge builders who remain largely anonymous to history except for the bridge's they built, making the Woodfern Road bridges all the more significant.

Because the spans share a common pier, they are evaluated as one structure. Both spans are significant.

Boundary Description and Justification: The two-span bridge is evaluated as individually significant. The boundary is limited to the structure itself, including the superstructures and substructures of both spans.

DESIGNER/PATENT JOSHUA DOUGHTY, CO. ENG. **BUILDER** JOHN W. SCOTT

SETTING / CONTEXT The bridge is one of two single-lane thru trusses that carry a country road across the river. The setting is sparsely developed rural with fields and scattered 19th- and 20th-century residences. The two trusses share a common masonry and earth-filled masonry pier. Immediately to the south of the pair of trusses is a third span, a concrete arch (18B0510), constructed in 1916.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span Pratt thru truss has masonry abutments. Built in 1902, the truss and its companion span (18B0511) are the youngest of 4 Pratt thru-truss highway bridges built in the county between 1885 and 1902. Builder John W. Scott was a small, a local fabricator from Flemington. Joshua Doughty was Somerset's first county engineer. The bridge is a well-preserved example of a historically significant type. It is the more complete of the 2 truss bridges at the crossing.

County Engineer Records and Plans. 18B0511.

PHYSICAL DESCRIPTION: The 84'-long, single-span, pin-connected, five-panel half-hip Pratt thru truss carries a single-lane road over the South Branch of the Raritan River and its flood plain. It is the southernmost of two nearly identical spans at the crossing. Comprised of rolled sections, the bridge has built-up box member top chords and end posts. The lower chords are paired eye bars. The verticals are angles with lacing, except for the hip verticals which are paired rods. The diagonals are paired eye bars, and the counters are single rods. The portal struts and bracing are angles with decorative lattice and builders plaques. The top struts are T-beams with steel rod lateral bracing. The I-beam floor beams are supported from the lower chord panel points by U-shaped hangers. The bridge abutments, wing walls, and pier are roughly-coursed red sandstone masonry, probably quarried locally. The bridge shares its northern pier with a similar skewed Pratt thru truss (18B0511).

The bridge retains its integrity of design, although a number of minor repairs have been made to the superstructure. In 1980 the county cut the lattice verticals at the three lower-middle panel points and added welded connecting plates. Steel angles were welded to the floor beams at the intersection with the stringers. Other alterations included the removal of the original railing (railing hangers still extant) and the addition of modern beam guide rails; the shifting of the southeast truss shoe from the roller plate; and a welded patch on the riveted cover plate of the southeast inclined end post. This span is more complete than the northern span.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Woodfern Road Bridge across the South Branch of the Raritan River is significant for engineering and method of construction (Criterion C). Built in 1902, the Pratt thru truss with its nearly identical companion truss to the north are the youngest of 4 surviving pin-connected Pratt thru-truss highway bridges built in Somerset County between 1885 and 1902, and the 9th youngest of 10 surviving thru trusses of all types. The Woodfern Road bridges retain integrity of design and has been in continuous use at the present site since the time of its construction. In the last decades of the 19th century, the Pratt truss type was built widely, and played a prominent part in the advance of a reliable network of overland transportation. It was well-regarded by engineers for its simplicity of design and easily determined structural action, and by the 20th century had gained almost universal acceptance for both railroad and highway spans. The Woodfern Road Bridge was constructed by John W. Scott, a small, locally-active bridge manufacturer from Flemington (Hunterdon County).

A bridge has spanned the South Branch of the Raritan River at the site since at least the mid-19th century. A 1860 map shows the bridge, and the minute books of the Board of Freeholders record repairs to the bridge as early as the 1880s. The proximity of the Old York Road, Somerset's main east-west road from the 17th to the 19th century, and Neshanic Station, established by the South Branch of the Central Railroad of New Jersey in the 1870s, made the crossing an important link in the rural transportation network.

The two trusses at Woodfern Road Bridge were built under two separate contracts by the same builder, John W. Scott. In July 1901 the Freeholders viewed the bridge and carried a motion to replace the southernmost truss (18B0512) with a new iron bridge "to be 80 ft. between abutments with 18 ft. roadway and of sufficient capacity to carry a 15 ton roller." Action was taken quickly: bids were advertised, prepared, and received within two weeks. Bidders on the project included Scott, the Easton Foundry and Machine Co., the Canton Bridge Co., W. Kirk, and the Berlin Construction Co. Scott was the low bidder on the project and received the contract at a price of $1600. In April 1902 the southernmost truss was completed. Two weeks after its completion, the Freeholders decided to also replace the northernmost span at Woodfern Road with a 100'-span bridge (18B0511). Scott again received the contract because "his plans submitted were for a heavier bridge than the plans of the lower bidders." The second truss was completed and accepted in September 1902.

SETTING / CONTEXT The bridge is located in a wooded, rural setting and carries one-way traffic over a small stream. It is on a quiet rural road that historically marked the division between East and West New Jersey. The bridge is on the line between Mercer and Somerset counties, and it was constructed as a joint-county project.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 12/05/90, Letter 6/30/95

SUMMARY The 6-panel rivet-connected Warren thru truss span on ashlar abutments is composed solely of angles, and is significant as an early example of both the truss type and method of fabrication. According to county records, floor beams are replacements, and the bearings were reinforced, but the trusses appear unaltered. The bridge is important in chronicling the evolution of metal truss bridge technology in the region. New Jersey Steel & Iron Co. of Trenton was a major bridge fabricating firm.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span, riveted, Warren pony truss has one span deeper than the other. The eastern span is a 67'-long, 5-panel truss, and the western span is a 85'-long and six panels. The bridge rests on preexisting rubble-coursed stone abutments and pier which may account for the unequal spans. It is technologically distinguished as a well-preserved example of its type because of its state of preservation and multi span configuration. It is one of 9 Warren pony truss spans in the county built 1910-1927.

INFOR MATION

Bibliography:
Condit, Carl. American Building Art: The 19th Century. New York: Oxford University Press, 1960. p. 118.
Somerset County. County Engineer Records. Bridge Card C0605.
Somerville County Democrat. "Freeholders Award Bridge Contracts." June 27, 1919.

Physical Description: The two-span, rivet-connected, Warren pony truss has spans of unequal lengths and depths. The eastern span is a 67'-long, five-panel Warren truss, and the western span is a 85'-long, six panel Warren truss. Both trusses consist of rolled steel members: the lower chords are angles with battens; the upper chords are box beam members with cover plates; the inward inclined diagonals are angles with lacing, and the outward inclined diagonals are angles with battens; and, the verticals are angles with battens. The abutments and pier are roughly-coursed masonry with rebuilt concrete seats. The bridge retains its original pipe railing, however a modern beam guide rail has also been added. Except for a few minor welded patches and repairs, the bridge has not been significantly altered.

Historical and Technological Significance: The Opie Road Bridge is the longest and best-preserved of at least six rivet-connected Warren pony truss highway bridges constructed in Somerset County built between 1915 and 1927. The Warren truss bridge type was patented in 1848 by two British engineers, James Warren and Willoughby Monzani. It differed from other trusses in that it did not have a vertical (compression) member and that alternate diagonals slope in opposite directions. Because some of those diagonals are compression members, the design was not well suited for pinned connections. With the perfection of the portable pneumatic equipment in the late-19th century, field riveting was possible, and the simple but rigid Warren truss come to the fore during the 1890s. During the early 20th century, steel Warren trusses appeared in rapidly growing numbers, and were used for both highway and railroad spans. The Opie Road bridge is a good representative example of Warren truss construction and engineering that made a significant contribution to the widespread use of metal truss bridges in the state.

The Opie Road bridge was constructed in 1919 by the F. W. Schwiers, Jr., Company of New York. It replaced an earlier bridge and was built on the preexisting masonry abutments and pier, accounting for the unequal lengths of the spans. In 1988, the county replaced the plank deck with an asphalt roadway and installed the beam guide rail.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The boundary is limited to the span itself, the superstructure and substructure.

SETTING / CONTEXT The narrow two-lane bridge spans a wide section of the river in the western part of the county. The area is rural with fields, pastures, and a farmhouse (c. 1820) to the west. A housing development (c. 1990) is being built to the east, but out of sight of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span, six-panel, riveted Pratt pony truss bridge has concrete abutments and cutwater pier. The bridge is one of the least altered of over 15 pony trusses built between ca. 1900 and 1927, and it is the only rivet-connected Pratt pony truss in the county. It is a well-preserved example of a historically and technologically significant type that is becoming increasingly rare in the state. The riveted Pratt is not a common 20th-century pony truss type, which adds to the value of the span.

INFOR MATION

Bibliography:
Condit, Carl. American Build Art: The 19th Century. New York: Oxford University Press, 1960.
Waddell, J. A. L. Bridge Engineering. New York: John Wiley and Son, 1916.

Physical Description: The 180'-long bridge consists of two six-panel half-hip Pratt pony trusses of equal length. The trusses are rivet-connected rolled steel sections. The upper chords and inclined end posts are built-up box beams with cover plates. The lower chords, verticals, and diagonals are angles with lacing. In addition, the bridge has angle outriggers. The floor beams and stringers are I-beams. The abutments and cutwater pier are concrete.

The bridge is well-preserved, and has not been significantly altered. The lower panel points and floor beam hangers have been repaired with bolts. A modern beam guide rail has been added.

Historical and Technological Significance: The Opie Road Bridge is one of the least altered of over 15 pony trusses remaining in the county from between ca.1900 and 1940. While this is the example that is a riveted Pratt pony truss bridge, it is a late example of riveted pony truss bridge technology, and it exhibits no unusual or noteworthy construction details. The Pratt truss bridge type was patented in 1844 by Thomas and Caleb Pratt of Boston, but did not gain popularity until the last half of the 19th century when it became one of the most common American truss types. Many engineers favored the Pratt truss type because of its easily determined structural action, simplicity and economy of metal. Others, like the opinionated J. A. L. Waddell, recommended its use for thru trusses, but did not recommend its use for pony trusses because of the lack of upper lateral support of the top chord. The perfection of riveted field connections brought the ascendancy of the Warren truss for pony truss spans after the turn of the century, and they are much more common than 20th century riveted Pratt trusses. This span is technologically significant because of it is an uncommon example of a rivet-connect Pratt pony truss span. It is also well preserved (criterion C).

No local records have been located to determine the builder or engineer for the Opie Road Bridge.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to the span itself, including the substructure.

SETTING / CONTEXT The bridge carries a 2-lane road over a small stream in a moderately developed suburban residential area west of the village of North Branch Station.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Built in 1930, the short, single-span concrete arch bridge with concrete balustrades is a representative example of a common bridge type. It is in poor condition with spalling, and has had utility pipes added to both the downstream and upstream elevations. Other examples of the bridge type exist in the county, and this one is not historically or technologically distinguished based on its date, size, and detailing.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 5-panel rivet-connected Warren with verticals pony truss bridge is supported on concrete abutments. The top chord and end posts are built up box members while the verticals and diagonals are composed of channels. The undocumented bridge exhibits standard details, and it is representative of a truss and construction type that is fairly common in the county. Some welded repairs have been made to the end posts. It is one of 9 riveted Warren pony truss bridges in the county and is not notable.

SETTING / CONTEXT The bridge is located on a bad curve and carries a quiet 2-lane road over a small stream in a unspoiled wooded setting on the south side of the mid-19th century state epileptic village now known as the New Jersey Neuropsychiatric Institute.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 8/3/90, Letter 6/30/95.

SUMMARY The 5-panel Parker pony truss bridge with bolted field connections is supported ashlar abutments. It is well preserved and is one of the few, and perhaps only Parker pony truss span in the state. In addition to its unusual truss type, with a polygonal top chord that accommodates strength at the center of truss and economy of material, the bridge is technologically significant for its early use of square-headed bolts for field connections. The only alteration appears to be removal of the railing.

SETTING / CONTEXT The bridge carries a 2-lane road over a small brook on the northern edge of the village of North Branch Station. To the south of the bridge is New Jersey Transit's Raritan Valley Line, formerly the Central Railroad of New Jersey, which also crosses Chambers Brook on a brick-lined arch (c.1848). Near the intersection of Station Road and Centre Street once stood the North Branch Depot. North Branch Station village has many older homes and structures, but most have modern alterations.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Constructed in ca. 1850, the single-span, brick arch with stone fascia bridge was built at the time the Somerville & Easton Railroad, predecessor of the Central Railroad of New Jersey, extended its line to White House and founded North Branch Station. The arch retains its integrity although the bridge was widened in 1935 with steel stringers on the upstream side. Due to its early date of construction and association with the early development of railroads in the county, the bridge is eligible.

INFOR MATION

Bibliography:
DeLeuw, Cather, and Co. New Jersey Transit Railroad Bridge Survey, 1991.
Somerset County Engineer. County Bridge Cards. 1935.
Snell, James. History of Hunterdon and Somerset Counties, 1881.

Physical Description: The bridge is a single-span elliptical brick arch with stone spandrel walls, abutments, and wingwalls. The stone masonry is random-course rubblestone with rusticated stone voussoirs. The bridge has been widened on the upstream side with two steel stringers inset into stone masonry at an angle to accommodate an extra lane leading into a Y-shaped intersection on the southern side of the bridge. Some concrete reinforcing has been made to the northeastern abutment to support one of the stringers. Beam guide rails have been added to the bridge. There is no evidence of previous railings or parapets. Some of the masonry has been repointed or covered with concrete, but not to a significant degree.

Historical and Technological Significance: The ca. 1850 brick arch bridge is the only known highway example of its type in Somerset County. Historically it appears to be associated with the founding of the village of North Branch Station, s small settlement that developed as a result of the 1848 development of the Somerville & Easton Railroad through the area. Although its construction is not documented, the bridge is the same type and style as a nearby span built by the railroad in 1848 to carry the line over Dumont Creek at Milepost 39.40. Although the brick arch bridge has been altered on one side, it still retains excellent integrity and is a technologically distinguished example of a brick arch span preserved in its original setting (criterion C).

Masonry arch bridges are not uncommon in Somerset County and were built from the 17th century into the 20th century. Most bridges made use of locally quarried stone, and although brick and other dressed stones were available, they were less frequently used due to the costs of shipping, a situation that began to change with the construction of canals and railroads. Although no construction records for the Station Road bridge have been located, it is possible that the bridge was constructed in 1848 when the Somerville and Easton Railroad, one of the precursors of the Central New Jersey Railroad, extended its line from Somerville to White House. A similar brick arch bridge with stone spandrel walls and a documented date of 1848 carries the railroad and a portion of the North Branch Station house over a branch of Chambers Creek just upstream from the highway bridge. The station building no longer exists, although a modern structure has been built on its foundations. The 1848 brick arch railroad bridge at milepost 39.40 is the earliest documented bridge in the 1991 NJT survey population, and it was evaluated as eligible.

County records indicate the bridge was widened with stringers at one quadrant in 1935.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to the arch span itself and the ashlar wingwalls. The 1935 addition does not contribute to the significance of the arch bridge.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The one-lane bridge carries an unimproved road over a small stream in a wooded, rural portion of the county dominated by "gentlemen farms" which preserve the historic agricultural character of the area.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 7' deep 5-panel rivet-connected Warren pony truss on ashlar abutments has been extensively altered with welded additional members. It was first rebuilt in 1938 and then again in 1988. The integrity of original design has been lost. The bridge is not historically or technologically distinguished as much of its fabric is mid- to late-20th century in origin. It is one of ten 20th-century Warren pony trusses in the county. Several others are in a more complete state of preservation.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span steel stringer bridge has been extensively rebuilt. Constructed in 1913, the bridge was originally a steel stringer with concrete slab deck and pipe railing. In 1973 the stringers were replaced, the railing removed, the bridge widened, the deck rebuilt, and beam guide rails added. The bridge abutments are a combination of older masonry and newer concrete construction. The bridge is not historically or technologically distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** WHELY MASON(?)

SETTING / CONTEXT The bridge carries two-lanes of traffic over Van Horn Brook near its confluence with the Millstone River. Van Horn Brook forms the southeast boundary of the Rocky Hill Historic District, a turn of the century village on the Delaware and Raritan Canal. The bridge is not contiguous to the concentration of historic buildings, but lies across the historic district's boundary.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Rocky Hill Historic District. 07/08/1982. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY Constructed in 1899, the well-preserved brick jack arch bridge has rolled I-beams and tie rods, and ashlar abutments with a plaque. It is individually eligible for listing in the National Register of Historic Places under Criterion C. It is within the period of significance of the Rocky Hill Historic District, and contributes to the district's historic character. In 1937 the roadway was widened slightly with narrow cantilevered extensions and the concrete parapets added, but the original jack arch portion of the bridge was undisturbed. It is a complete example of brick jack arch technology.

INFOR MATION

Bibliography:
ONJH. Somerset County: Rocky Hill Historic District National Register nomination, 1982.
Somerset County Engineer. Bridge File E0104.

Physical Description: The 29'-long bridge is composed of rolled I beam stringers with well-preserved brick jack arch fill. The stringers are tied together to counter the lateral thrust of the arches by tie rods anchored through the fascia members by square head bolts. The fascia on the downstream side is composed of stacked I members while that on the upstream side is stacked toe-in angle. The bridge rests on high, well-preserved ashlar abutments that include a date stone inscribed "Built A.D. 1899 Whely, Mason." In 1937 a new concrete deck was installed, and at that time the deck was cantilevered about one foot on each side to widen the roadway. The concrete parapet with scoring on the roadway face was added at that time. The 1937 work does not appear to have modified the original configuration. Beam guide rail marks the curved approaches to the span.

Historical and Technological Significance: The bridge ranks as one of the longest and most complete examples of brick jack arch technology in the region. In addition to its technological importance, the bridge crosses the boundary of the Rocky Hill Historic District, and it was built within the period of significance of the district and is thus a contributing resource.

The jack arch is a construction detail initially developed during the second quarter of the nineteenth century as a means of both strengthening and fireproofing beams in buildings. The shallow arches span between rolled stringers to add rigidity, some load-carrying capacity, and protection for the stringers. Brick jack arches, which are more common in some areas of the state than others, were used from about 1885 until about 1905. From about 1905 until the first world war jack arches were executed in concrete rather than brick. The 1937 alterations to the deck and parapet did not impact the original stringer-jack arch arrangement. The River Road bridge is the longest and one of the best preserved of the less than half a dozen stringer spans with brick jack arches identified in the southern two-thirds of New Jersey.

Boundary Description and Justification: Since the feature that the bridge crosses is a southeast boundary of the Rocky Hill Historic District, the bridge and its surroundings are evaluated as significant. The bridge is a contributing structure to the historic district, and it is also individually significant.

SETTING / CONTEXT The bridge carries a 2-lane road over tree-lined Pike Brook near its confluence with the Millstone River. The bridge lies within the River Road Historic District, an area of well-preserved 18th, 19th, and early-20th century residences and farms bordering the Millstone River. To the northeast of the bridge is an early farmhouse with associated outbuildings.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Not Individually Eligible. Listed. River Road Historic District. 03/21/1991. Contributed.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Built in 1927, the single-span encased concrete stringer with incised concrete parapets and concrete substructure is within the dates of significance of the River Road Historic District (1740-1939). The bridge contributes to the historic district as a representative example of a bridge type constructed widely in the county in the 1910s and 1920s. The bridge is indicative of the local effort to improve farm to market roads, and is significant to the district's transportation history.

INFOR MATION

Office of New Jersey Heritage. River Road Historic District Nomination, 1991.

PHYSICAL DESCRIPTION: The two-lane bridge is a single-span encased steel stringer with incised concrete parapets and concrete substructure. The incised parapets have a rectangular pattern, and are stepped over the abutments. A stone plaque inset in the parapet reads "O. Smith, Jr., Co. Engineer. Snook Bros. Contractors. 1927." The stringer encasing is spalling and the bottom flanges of the I-beams are exposed. The bridge has a concrete deck with an asphalt road surface.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The 1927 bridge is within the River Road Historic District, a rural district of 18th, 19th, and early-20th century residences and farms paralleling the Millstone River. The bridge is not rated in the historic district nomination but falls within the district's period of significance (1740-1939). The bridge is indicative of the highway improvement campaigns of the post-World War I period, and the increasingly important role of automobile transportation in the lives of rural dwellers. Encased steel stringers were built widely in Somerset County in the period between 1915 and 1929; at least 17 similar short-span bridges are known to survive. Except for some deterioration of the concrete encasing, the Pike Brook bridge appears unaltered. The bridge is not individually distinguished, either historically or technologically. it is a common type and design. Its significance is solely based on the fact that it is located in a National Register-listed historic district and that it was built within the period of significance of that district. It is not a major element within the district, and it was not mentioned in any section of the 1991 nomination.

Boundary Description and Justification: The bridge is located within a listed National Register historic district. Thus the bridge and its setting are evaluated as significant. For a complete description of the district boundaries, please refer to the National Register file at the ONJH.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The two-lane bridge carries a dirt road across a small creek at a southern entrance to the James B. Duke Estate. The bridge is at the intersection of Roycefield Road and Dukes Parkway. The area is undeveloped and wooded. Upstream from the bridge is a small dam and waterfall. The bridge matches the architecture and landscaping of the 327-acre estate, which was intended to mirror Duke's love of nature and art, and provide an escape from his work in New York City.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Duke Estate Historic District. Contributing.

CONSULT DOCUMENTS SHPO Finding 09/16/83, Letter 03/12/01. DOE 02/12/1985.

SUMMARY The reinforced concrete deck arch bridge is finished with rubble-coursed stone spandrel walls and parapets. The ring stones are set in a pattern of alternating a long and two short stones. The rustic bridge is historically associated with J.B. Duke's development of his estate in the first decades of the 20th century. It includes a number of other rusticated bridges, although each is individually different. The 2,00-acre estate is well preserved and is a potential historic district. The bridge is a contributing element to the Duke Estate Historic District, eligible for listing in the National Register of Historic Places under Criteria A and C.

INFOR MATION

Bibliography:
ONJH. Files by Subject: James B. Duke Estate, National Register Nomination, 1987.
Jenkins, John Wilbur. James B. Duke, Master Builder. New York: George H. Doran Co., 1927.

Physical Description: The 28'-long bridge is a single-span reinforced concrete elliptical arch with stone spandrel walls and parapets of rubble-coursed fieldstone of various sizes, shapes, and coloration's. The ring stones are an alternating pattern of one long stone and two short stones. At the approaches the parapets have rounded end posts. The bridge carries an unimproved road through a wooded portion of the J.B. Duke estate. The bridge is in excellent condition.

Historical and Technological Significance: The concrete arch bridge finished with stone spandrel walls and parapets is located within the boundaries of the James B. Duke Estate. The estate is considered National Register-eligible for its association with tobacco magnate Duke, and for its architectural significance as an outstanding example of a Gilded Age country estate built in a romanticized style. The landscaping, including walls and bridges which were designed as an integral part of the landscape scheme, are significant contributing elements to the estate's significance. The Roycefield Road bridge is specifically mentioned in the 1987 draft National Register nomination.

From 1893 until his death in 1925, one of James Duke's passions was the development of his 2000-acre country estate in Somerset County. In 1903 Duke hired the architectural firm of Buckenham and Miller of New York City to design the walls, pathways, bridges, fountains, well-houses, and buildings. One of the styles chosen for some walls and bridges was the "boulder style," popularized by Frederick Law Olmsted. Two teams of Italian masons from Long Island, Curcio Brothers and Barone and Darienco, constructed the rustic walls and bridges. No two bridges in the estate are exactly alike, and the Roycefield Road bridge is one of at least a half dozen bridges on the estate property. It is a contributing resource to the historic character of the well-preserved estate, which remains in the Duke family.

Boundary Description and Justification: The bridge is on the road that forms the west boundary of the Duke's Farm Historic District. It is a contributing resource to that district. The bridge and its surroundings are evaluated as significant.

Wrought Iron Bridge Company. Illustrated Pamphlet of Wrought Iron Bridges Built By Wrought Iron Bridge Company, Canton, Ohio. Canton, OH: Wrought Iron Bridge Co., 1885.

PHYSICAL DESCRIPTION: The Nevius Street Bridge is a single-lane, two-span bridge consisting of two nearly identical 10-panel, pin-connected, double-intersection Pratt thru trusses, each 150'-long out-to-out, and 23' in depth. The bridge has an 18'-wide roadway, and a cantilevered sidewalk with lattice railing on the upstream side. The bridge members are rolled metal sections; it has not been determined whether the sections are wrought iron, steel, or both. The lower chords are loop-welded eye bars, and the upper chords and inclined end posts are two channels with riveted cover plate. The hip verticals consist of three rods and all other verticals are channels with riveted lacing. The truss diagonals are paired eye bars and the counters with turnbuckles are paired rods. Where the counters and diagonals intersect the verticals there are metal shaped rings, commonly called "donuts." All panel point connections are made by steel pins with turned ends and tightening bolts.

The trusses have A-shaped portal bracing with decorative lattice, knee bracing and builders' plaque. The struts are I-beams, and the top-lateral and bottom lateral bracing are rods. The trusses have riveted-girder floor beams with steel stringers. The floor beams are hung from the lower panel points by U-shaped hangers. The deck is corrugated steel plate with asphalt road surface. The trusses have pipe hand railing and steel beam guard railing. The masonry abutments and cutwater center pier are coursed red sandstone, probably quarried locally. Both the south and north abutments show signs of repair with modern cement-based mortars. The bridge's south earth-filled approach is approximately 132-feet long with coursed red sandstone retaining walls and parapet topped with a pipe railing.

Alterations to the trusses have been minimal. Most of the changes appear to have taken in place in 1938. In that year, county crews installed new truss expansion bearings and concrete seats; rebuilt the floor beam hangers with welded connections; sealed the lower panel points with concrete in the space between the verticals' channels; and added the existing steel beam guide rails. Sometime between 1938 and 1970 the corrugated steel and asphalt deck replaced a wood plank deck. Angles have replaced some of the lower lateral bracing rods.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Nevius Street Bridge across the Raritan River is significant for its engineering and method of construction. Built in 1886, it is the one of the two oldest surviving metal truss highway bridge in the county, and the oldest surviving metal truss bridge still in continuous use. It represents an influential period of innovation and expansion in the development of American metal truss bridge building technology and was constructed by a nationally recognized bridge fabricator, the Wrought Iron Bridge Company of Canton, Ohio. The truss retains a high degree of integrity of design, and is one of the least altered and longest of the more than 20 surviving trusses in the county. The bridge is also the only double-intersection Pratt type truss in the county, a type increasingly rare but once employed widely by railroads in the middle decades of the 19th century. Metal trusses like the Nevius Street Bridge represent a noteworthy period of economic and industrial development in the county's history, and played a prominent part in the advance of a reliable network of overland transportation.

A bridge has spanned the Raritan River at the site of the Nevius Street Bridge, also known as the Raritan Bridge, since at least the mid-1840s. The first bridge was a six-span timber structure that connected the agricultural countryside of Hillsborough Township on the south side of the river with the village of Raritan on the north bank. Raritan's location and its abundance of water power led to its industrialization in the period between 1840 and 1880.

The Nevius Street Bridge, erected in 1886, was in keeping with the town's growing industrial and urban character. In February, the Freeholders met at the old wood bridge and agreed that it had become dangerous to the traveling public. They authorized immediate makeshift repairs not to exceed $300, and moved to build a new bridge as soon as possible in the spring. In May, the Freeholders appointed a committee to advertise for proposals for both wooden and iron bridges, and for masonry substructures. The instructions were specific that if the committee excepted a proposal for an iron bridge it was to be for "2 spans of 150' each, a high truss of 80 lbs. pressure to the sq. ft. with a factor of 4, planked with Georgia pine 3" thick, the bridge to be raised 2-1/2" higher (sic)."

Two weeks later, the Freeholders awarded the superstructure contract to the Wrought Iron Bridge Company of Canton, Ohio, the lowest bidder at $7040. Substructure contracts were usually let separately from superstructure, and the masons prepared the abutments, piers, and wing walls, before the truss erection crews arrived at the site. In the case of the Nevius Street Bridge, the Freeholders awarded the contract for the substructure to two local masons, William W. Smith and Richardson Farrier. In a last minute change of plans, the Freeholders also accepted the petition of local citizens to widen the bridge roadway from 16 to 18 feet.

The Nevius Street Bridge was also the first time that the Board of Freeholder Minutes mention the employment of a professional civil engineer, F. A. Dunham, to supervise the construction of a bridge. Work on the substructure of the new bridge continued through the summer of 1886. In mid-October, the truss arrived from the Wrought Iron Bridge Company's shops in Canton. On November 17, 1886, the Freeholders accepted the Nevius Street Bridge as complete and made final payments for the masonry work, superstructure, grading, and engineering.

The Wrought Iron Bridge Company of Canton, Ohio, specialized in the construction of highway bridges. Organized in 1864 by David Hammond, the company was one of the first wrought iron truss manufacturers, and continued in existence for 36 years before being absorbed by the giant American Bridge Company in 1900. The company claimed in its promotional literature to have constructed trusses in 30 states, mostly east of the Mississippi River. In Canton, the fabricator had shops for the drafting, laying out, shearing, drilling, punching, and riveting of truss members, but did not roll its own iron or steel. The Wrought Iron Bridge Company was recognized as one of the most significant regional manufacturers of iron and steel trusses because of its workmanship and prolificacy. One other Wrought Iron Bridge Company truss is known to exist in Somerset County; the Higginsville Road Bridge over the South Branch of the Raritan River in Hillsborough Township is a well-preserved Pratt truss constructed in 1893. According to the company's 1885 trade catalogue, at least 10 other Wrought Iron Bridge Company trusses were built in New Jersey prior to 1885.

Boundary Justification and Description The bridge is individually listed in the National Register, and the boundary is limited to the span itself. The four quadrants of the bridge are also included in the Duke Farms Historic District that has been determined eligible through a SHPO finding.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed rivet-connected 4-panel Warren pony truss bridge is a complete example of its type, but its design is typical of the period. It is composed of channels and plates for the chords, and of angles joined by battens for the diagonals. The Warren is the most common 20th-century truss type for highway bridges. The newest of the 10 Warren pony truss spans in the county, it is an extremely well preserved example of the historically significant bridge type, and it is thus notable.

INFORMATION

Bibliography:
Somerset County Engineer: Bridge File: E141.
Musti, J. Somerset County New Jersey 1688-1930. Camden, N.J., 1930.

Physical Description: The skewed 62'-long riveted Warren pony truss bridge is supported on a concrete substructure. The span is extremely well preserved. The upper chords and inclined end posts are built up box members with channels with cover plate and lacing. The diagonals are toe-down angles with battens, and the lower chords are toe-up angles with battens. Asymmetrical gusset plates are placed on both sides of the lower panel points, and they too are stiffened with a batten plate. The floor beams and stringers are rolled I sections. Lattice railings are still in place on the inside face of the trusses. As complete as the trusses is the rural setting of the bridge, which services and unimproved road.

Historical and Technological Significance: The Warren pony truss bridge on Jackson Road was built in 1927, and it is the latest of the surviving examples of metal truss bridges in the county. While exhibiting on innovative or patented details, the span is technologically and historically significant as a well preserved survivor of the last years of metal truss bridge erection in the area (criterion C). It was apparently designed by County Engineer Oscar Smith, Jr., who succeeded longtime County Engineer Joshua Doughty, and it was built at a time when most county-designed spans were encased stringers. There is no indication that this bridge was moved to Jackson Road from another location.

Prior to the widespread acceptance of rolled steel stringer and reinforced concrete arch bridges in the 1910s, the Warren pony truss was the most common early-20th century highway bridge for crossings of less than 100'. The Warren truss bridge type was patented in 1848 by two British engineers, James Warren and Willoughby Monzani. It differed from other trusses in that it did not have a vertical (compression) member and that alternate diagonals slope in opposite directions. Because some of those diagonals are compression members, the design was not well suited for pinned connections. With the perfection of the portable pneumatic equipment in the late-19th century, field riveting was possible, and the simple but rigid Warren truss came to the fore during the 1890s. During the early 20th century, steel Warren trusses appeared in rapidly growing numbers, and were used for both highway and railroad spans. However, by the end of the 1920s. few, if any, metal pony truss highway bridges were being built in New Jersey.

Boundary Description and Justification: The bridge is evaluated as individually distinguished, although its rural setting does offer fine integrity of setting. The significant boundary is limited to the span itself, both the superstructure and substructure.

SETTING / CONTEXT The one-lane bridge crosses the picturesque Millstone River in a rural area that retains its 19th century agrarian character. The span is located on the boundary of the Griggstown Historic District. The boundary is the middle of the river, thus half the bridge is outside the listed historic district.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Griggstown Historic District 08/02/1984. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span Pratt half hip pin-connected pony truss bridge dates to 1903, but it has been strengthened and repaired at least twice (1938; 1978). It is supported on the west end by an ashlar abutment from an earlier span, but the pier and east abutment are concrete. Although built by Dover Boiler Works of Morris County, the bridge has been so altered by welded additional members and replacement flooring system that it has little design integrity. Alterations compromise its technological significance. Because of the alterations and the district boundary splitting the bridge, it is not contributing.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The two-lane bridge spans Peters Brook within Somerville's Peters Brook Park, a recreational area and greenstrip developed in the early 20th century. To the south of the bridge is a playground and swimming pool. The surrounding neighborhood is mixed-use commercial and residential (c.1890-1930), with many modern intrusions.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span, reinforced-concrete arch bridge with sidewalks has a concrete pier and circular decorative patterns on the closed spandrel walls. The balustrades have been removed and replaced with beam guide rails, except for 3 concrete end posts topped by decorative balls. The bridge is in poor condition with cracks and spalling. It is 1 of 6 concrete arches built in Peters Brook Park between 1905 and 1928. The bridge is not historically or technologically distinguished.

DESIGNER/PATENT H. VAN EMBURGH, CO. ENG. **BUILDER** CROOK SUTTON

SETTING / CONTEXT The two-lane bridge spans Peters Brook in Peters Brook Park, a municipal recreation area and green strip in downtown Somerville. Next to the bridge are playing fields and a flower garden. The surrounding area is residential with single-family homes and apartment buildings (c.1850-1930) with many modern intrusions and additions.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed single-span bridge is a ribbed closed spandrel arch with architectonic details including abutment pylons with Moderne styling, masonry approach walls with concrete balustrades, and cantilevered sidewalks with wrought-iron railing. The bridge was originally built in 1925, but in 1932 the profile of the bridge was raised and the pylons rebuilt inkind. Gunite was also applied to the bridge over steel mesh work. The county-designed bridge is one of the few state examples of its type.

INFOR MATION

Bibliography:
Somerset County Engineer. Bridge File F0806.
Condit, Carl. American Building Art 20th Century, 1960.

Physical Description: The well-detailed and well-proportioned ribbed arch bridge has a 63'-long clear span and is composed of five elliptical reinforced concrete ribs on a concrete footing. The back walls are also concrete, but the wing walls are rubble stone. The arched ribs have a rise of 15'. The sidewalks are carried on encased brackets and enclosed by a metal fence-like railing set between concrete posts. The ends of the bridge are marked with massive concrete piers with brushed finish concrete panels. The piers were originally topped by decorative metal lamp posts and lamps with plain globes. The approaches are marked by concrete balustrades. The roadway over the bridge is inclined with a 4.8% rise from north to south. The profile was changed in 1932.

Historical and Technological Significance: The 1925 reinforced concrete ribbed arch bridge designed by Somerset County Engineer H. Van Emburgh and his staff is the only documented example of a county-built ribbed arch span in the region (criterion C). Although not technologically innovative, as the ribbed arch had been in use in this country since the 1910s, it is not a common bridge type in New Jersey. The use of reinforced ribs saved material, although it necessitates a deeper deck, and it produces an aesthetically pleasing span. This well-detailed bridge is located in a small urban park in Somerville. The profile of the bridge was changed in 1932, but the details of the original design were reused or reproduced. With the exception of the loss of the originally specified lights at the four corners of the bridge, the span appears to be complete.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to the structure itself.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 3-panel pin connected half hip Pratt pony truss with counters built by the Penn Bridge Co. of Beaver Falls. PA was the most complete example of the popular late-19th century truss type in the county. In 1993 the truss was dismantled and the superstructure rebuilt as a glulam slab bridge. The truss now serves as railings for a new, wider bridge. Although the original floorbeams are still present the original flooring system is gone. The ashlar abutments remain. The bridge is no longer individually eligible for listing in the National Register of Historic Places It is, however, a contributing element of the Griggstown Historic District under Criterion C.

DESIGNER/PATENT UNKNOWN **BUILDER** DELAWARE & RARITAN CANAL

SETTING / CONTEXT The bridge is an aqueduct serving to carry both River Road and the neighboring Delaware and Raritan Canal over Six Mile Run. The area is rural with fields and woods. To the north is the 19th-century crossroads village of Blackwells Mills with a restored canal lock tenders house maintained by the Delaware and Raritan Canal State Park. The canal right-of-way is listed in the National Register. Since the structure carries the listed resource, it is interpreted as also being eligible.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. D&R Canal. 05/11/1973. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span stone arch was constructed as part of the Delaware and Raritan Canal in 1834. The canal operated until about 1940 and primarily carried Pennsylvania coal to New York. After its closing, the state acquired the canal for a park. In 1984 the aqueduct, which carries the road and the canal/towpath at different levels, was restored. It is one of the largest of at least 16 stone arch structures along the canal. It is listed on the National Register because it carries the canal r-o-w.

SETTING / CONTEXT The Millstone Causeway carries a two-lane county road and sidewalks over the Millstone River and its floodplain. The bridge spans between the villages of Millstone on the west side and East Millstone to the east. The middle of the river forms the eastern boundary of the 19th-century Millstone Historic District, thus the bridge lies partially within the district. East of the causeway is the Delaware and Raritan Canal, which forms the western boundary of the East Millstone Historic District.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible. Listed. Millstone Historic District. 09/13/1976. Contributed.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 881' Millstone Causeway has 3 encased steel-stringer main spans over the Millstone River, and 25 short concrete T-beam spans over the river's floodplain. The bridge has a concrete substructure, concrete balustrades, and handsome concrete light standards with original double luminaries. The bridge is at a historically significant river crossing, and it is one of the largest bridges of its period in the county. Its state of preservation and size make it a significant local example of its type.

INFOR MATION

Bibliography:
Somerset County Engineer. Bridge File # G0505.
Mustin, M. Somerset County New Jersey. 1930.

Physical Description: The 881'-long viaduct has three encased steel stringer main spans over the Millstone River and 25 short reinforced concrete T beam spans over the flood plains. All are supported on a concrete substructure composed of concrete abutments with wingwalls and three-column concrete bents. The same concrete balustrade with circular-headed openings and scored posts is used the entire length of the span, and it is severely deteriorated in several sections. The most significant detail of the span is the five sets of concrete light standards. Each has a square base scored with Arts and Crafts-inspired decoration and a pylon post fitted with a two-arm luminaire. The posts and lamps rank among the most handsome of any bridge lighting detail in the state. The bridge is deteriorated but it does not appear to have been altered.

Historical and Technological Significance: The Millstone Causeway, designed for or by County Engineer Oscar Smith and built in 1930, is the largest and most ornamental of the over fifty concrete-encased stringer bridges in the county. While not technologically innovative or noteworthy, the bridge incorporates most of the architectonic features found on smaller and less ambitious bridges from the period between the world wars. The most notable feature of the span is the five sets of light posts. Finished in Arts-and-Crafts detailed cast concrete, the well-proportioned and well-detailed posts are fitted with two-arm luminaries that are as fine as any in the state (criterion C). Once a fairly common detail on both county and state bridges, such lighting fixtures are now rare. The bridge was fabricated by the American Bridge Company and built by James E. Gano, a local contractor. Oscar O. Smith, Jr., County Engineer, supervised the construction.

The bridge is at a historically significant river crossing that has had a bridge since the mid 18th century. The bridge crosses the Millstone River between two National Register-listed districts. Though the causeway lies partially within the Millstone Historic District, the bridge is not within the district's period of significance. The Millstone Causeway does not directly contribute to the historic character of either district and is thus noncontributing to the district. But, it is individually significant as a large, well-detailed, and well preserved example of a bridge type that played an important role in the road improvement campaigns of the 1920s and 1930s.

Boundary Description and Justification: The west side of the bridge is located in the National Register-listed Millstone Historic District, which identified the middle of the river as the boundary. Thus the west half of the bridge is located in a significant setting. A more accurate boundary for the district would be the west bank of the river which would then mean that the setting of the entire limit of the bridge is in a historic setting.

DESIGNER/PATENT H. VAN EMBURGH, CO. ENG. **BUILDER** W. I. HOUGHTON

SETTING / CONTEXT The narrow two-lane bridge spans a small brook just west of the Millstone River. The bridge is in a small wooded area next to the river in southern Manville Borough. The residential and commercial neighborhood to the west is heavily developed. A concrete dam extends between the bridge's upstream wing walls.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span encased steel stringer bridge with concrete substructure is significantly altered and in poor condition. The downstream parapet has been removed and beam guide rails added on both sides of the roadway. The abutments and concrete encasing are seriously spalled. Encased steel stringers are a common 1920s bridge type in Somerset County. The bridge is not historically or technologically distinguished.

SETTING / CONTEXT The 4-lane bridge spans the Raritan River between Manville Borough and Bridgewater Township. The bridge is in a major industrial area near the Johns-Manville asbestos factory (closed), the National Starch factory, and the main line of Conrail. Open fields next to the bridge have been used for the dumping of spoils from industrial processes.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 9-span bridge has three encased steel stringer main spans over the main channel of the river, and 6 arch approach spans to the south over the river's flood plain. The bridge has been highly altered and has at least 3 periods of construction. The approach spans are stone arches (1896) with stringer/concrete (1934) and box beam/stringer (1975) additions. The main spans (1934) were widened with box beams (1975). The bridge is not historically or technologically distinguished.

INFOR MATION

Bibliography:
Somerset County - 250 Years. Somerville, NJ: Somerset Press, 1938.
Somerset County Engineer. Bridge Plans and Cards.

Physical Description: The nine span bridge consists of three main spans over the Raritan River and six approach spans over the flood plain to the south. The bridge represents three major periods of construction. It was initially built in 1896 with six stone arch approach spans and a Pratt thru truss main span. In 1934, the truss was removed and encased steel stringers and a new concrete substructure erected in its place. At the same time, the arches were widened on the upstream side with encased stringers. The deck was rebuilt and concrete balustrades were added to the bridge. The balustrade posts had light standards and lanterns (since removed), and a commemorative monument with the county seal and builder's plaque was erected near center-span. In 1974, the bridge was widened to four lanes with a median barrier. The approach spans were widened on the downstream side with prestressed box beams, and the main spans with stringers. The downstream balustrade was removed, and a concrete barrier parapet with pipe railing was added. The stone arches were sprayed with gunite.

Historical and Technological Significance: Built in 1896 as a pin-connected thru truss main span with stone arch approach spans on the south side, the bridge, known locally as the Van Veghten Bridge, has been significantly altered and bears little resemblance to the original, historic structure. It does not have integrity of design. In 1934 the thru truss was removed, the substructure was rebuilt, and a new encased rolled stringer superstructure was placed. The stone arch approach spans were encased in concrete and widened on the upstream side with stringer additions. A standard-design concrete balustrade was installed on both sides of the widened bridge. Memorial plaques were set in a classically inspired frontispiece atop one of the balustrade posts near the center of the upstream side. The 1934 rebuilding was done by James E. Gano. In 1974 the bridge was widened again, and at that time the downstream balustrade placed in 1934 was lost. the 1974 work was designed by A. G. Lichtenstein & Associates. The bridge has lost its original integrity of design, and thus its historical and technological significance. The 1934 and 1974 additions are not historically nor technologically significant.

The bridge is at the location of one of the earliest bridges across the Raritan River in Somerset County. The bridge is known locally as the Van Veghten Bridge, after an 18th-century family that lived near the site. No 18th-century bridge fabric is known to survive.

SUMMARY The bridge is a make-shift of old and new structural components, and is a thru girder with floor beams. County records indicate that the superstructure was rebuilt in 1927, stringers replaced in 1981, and deck replaced in 1985. Concrete piers support the bridge at center span, and floor beams are spaced at uneven intervals and are attached to the rolled I-section girders by U-shaped hangers. The abutments are masonry extended with concrete. The span is not technologically noteworthy.

SETTING / CONTEXT The two-lane bridge with sidewalks spans the Passaic River, which forms the border between Morris County and Somerset County. The bridge is located in a mid-20th century suburban residential neighborhood. Most of the homes have modern additions and alterations.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span, concrete-encased steel stringer bridge with concrete balustrades and substructure was constructed in 1931 as a joint-county project of Morris County and Somerset County. The bridge is in poor condition with concrete spalling exposing the lower flanges of the stringers. The bridge is a common 20th-century bridge type, similar to bridges found throughout the state. It is not historically or technologically distinguished.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span 1925 steel thru girder bridge with partially encased floor beams has been significantly altered by widening with steel stringers on the downstream side (1982). In order to widen the bridge the downstream girder was cut down and converted into a stringer the same depth as the ones used for the widened extension. The bridge has a concrete substructure and beam guide rail railings. It is heavily altered and is also not historically or technologically distinguished.

SETTING / CONTEXT The two-lane bridge spans Green Brook, which forms the border between Somerset County and Union County. The surrounding neighborhood is late-19th and early-20th century vernacular residential housing with modern additions and intrusions. To the south is a commercial area along NJ 28, Plainfield's Front Street. Plainfield and North Plainfield grew rapidly in the late 19th and early 20th centuries as a response to suburbanization promoted by railroads and industrial expansion.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span multi-girder bridge was constructed in 1903 by a regionally significant bridge manufacturer, the Dover Boiler Works. The bridge retains its integrity of design with riveted girders and brick jack arches that are deeper for the roadway than the sidewalks. The bridge rests on ashlar abutments. In 1924 the railings with fluted cast iron posts were added. The bridge is associated with a historical period of suburban expansion in Plainfield and North Plainfield.

INFOR MATION

Bibliography:
Somerset County Engineer. Bridge File M0903.
Darnell, Victor. Directory of American Bridge Building Companies 1840-1900. 1984.

Physical Description: The 49'-long bridge is a well-preserved example of a built-up multi deck girder span with brick jack arches. The span, which carries the roadway and two flanking sidewalks, is supported on ashlar abutments. The girders have X-pattern lateral bracing. The jack arches between the girders are of two depths; the shallower of the two is used under the sidewalks while those under the roadway are deeper. The large number of rivets on girders is explained by the rivet-connected angles that serve as jack arch skewbacks. The handsome iron picket railing with cast iron posts was placed in 1924.

Historical and Technological Significance: The 1903 multi-girder bridge is a complete example of its type and is also a good example of brick jack arch technology. The built-up multi-girder bridge was used in New Jersey for a brief period between the 1890s and about 1910. It fell out of use after the improvement of rolled steel stringers. Brick jack arches, which add some load-carrying capacity to the span, also ceased to be used about the same time. The well-preserved bridge is thus technologically distinguished as an example of bridge building technologies that were eclipsed by others early this century. It is also the work of a regionally noteworthy fabricator -- Dover Boiler Works of Dover (Morris County), New Jersey. They company began fabricating bridges from stock shapes in 1901, and they continued to do so until at least the 1920s. Not more than a dozen examples of their work have been identified to date.

Boundary Description and Justification: The span is located in a late-19th century residential area, but numerous alterations to the dwellings diminish the architectural significance of the setting, which consequently does not appear to possess historic district potential. the span is evaluated as individually distinguished, and the boundary is limited to the structures, superstructure and ashlar portion of the substructure itself.

DESIGNER/PATENT JOSHUA DOUGHTY, CO. ENG. **BUILDER** ARTHUR E. SMITH

SETTING / CONTEXT The two-lane bridge with sidewalks spans Green Brook on the border between Somerset County and Union County. South of the bridge is Plainfield's downtown, and north of the bridge is a residential neighborhood with single-family homes and apartment buildings. The buildings date from the late-19th and early-20th centuries but few retain their historic integrity.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span reinforced-concrete arch bridge has concrete balustrades with vase-shaped balusters. The bridge is 1 of at least 7 similar arches built in the county between 1910 and 1917. The bridge is in poor condition with spalling and numerous concrete repairs to the balustrades. Although the bridge retains some architectonic features, it is not a historically or technologically distinguished example of the bridge type. It is one of 20 examples of its type in the county.

SETTING / CONTEXT The two-lane bridge with sidewalks spans Green Brook on the border between Somerset County and Union County. South of the bridge is downtown Plainfield, and north a residential neighborhood of North Plainfield. Next to the bridge is a large parking lot. Most of the neighboring buildings date from the late-19th or early-20th century, but have been significantly altered and modernized.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span multi-deck girder bridge was constructed in 1900 by the NJ Steel & Iron Co. of Trenton. The original plans show a lattice railing that has since been replaced by a picket rail on one side of the bridge and beam guide rails on the other. In 1990 the county repaired the deck and made welded repairs to the girders. The bridge is not historically or technologically distinguished. Gerard Avenue over Green Brook (18M0903) is a more extant example of the bridge type.

SETTING / CONTEXT The bridge carries a 1-lane, 2-way road in a wooded undeveloped area over abandoned Conrail r-o-w, formerly r-o-w of the New Jersey Cutoff of the Delaware Lackawanna & Western Railroad. The NJ Cutoff was constructed to improve transportation of anthracite coal from Pennsylvania to markets east. A significant engineering achievement, the line was constructed with major cuts and fills, and avoided creating any highway railroad grade crossings along its 28.45 mile length.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94, Letter 03/12/01.

SUMMARY The elliptical concrete deck arch bridge supported on a concrete substructure has reticulated concrete balustrades. The handsome and unaltered span is one of 7 arch bridges built in the county as part of the 1908-1911 development of the NJ Cutoff by the DL&W RR. Others are in Warren Co. The cutoff is a technologically significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The bridge is not individually eligible for listing in the National Register of Historic Places, but is eligible under Criterion C as a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District.

Lefferts, H. Leedom Jr., and Piefer, David R., Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. 1979.

Physical Description: The reinforced concrete elliptical arch bridge with a high rise is flanked by reticulated concrete balustrades. The arch spans 66', and carries an 18' wide road. The date of construction, 1911, is inscribed on the fascia. The span appears unaltered.

Historical and Technological Significance: The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties from Slateford, Pennsylvania to the DL&W mainline near Lake Hopatcong. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information

A. G. Lichtenstein & Associates, Inc. performed initial survery.
NJDOT updated data 03-01-2001.

Correspondence.Unit@DOT.State.NJ.US
November 12, 2002

gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the old 1851 Warren Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152, and 1911155 in Sussex County). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams (1900C18).

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) in Knowlton Township and the Paulins Kill Viaduct (Milepoint 70.63, near Hainesburg in Knowlton Township). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through (viaduct not included in the bridge survey because no roadway is associated with it). It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical

connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

DESIGNER/PATENT DL&W OFFICE OF ENGINEERING **BUILDER** DAVID W. FLICKWIR

SETTING / CONTEXT The bridge carries a 2-lane road over a lake inlet in a wooded area. The bridge is beneath a concrete arch span and high fill carrying the New Jersey Cut-Off of the DL&W Railroad across a valley and lake. That arch span was not inventoried, but is pictured. The Cutoff improved the movement of Pennsylvania anthracite coal to markets east. A significant engineering achievement, the lines was constructed with major cuts and fills, and avoided creating any highway railroad grade crossings along its 28.45 mile length.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94, Letter 03/12/01.

SUMMARY The 2-span skewed reinforced concrete culvert span with concrete substructure has no railings. An example of a common bridge type, the span is not individually significant, but is an original feature of the 1908-11 NJ Cutoff of the DL&W RR, a significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The culvert accommodates flow on each side of the cutoff, which crosses the lake. The structure is not individually eligible for listing in the National Register of Historic Places, but is eligible as a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District under Criteria A and C.

INFOR MATION

Lefferts, H. Leedom Jr., and Piefer, David R., Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. 1979.

Physical Description: The skewed 2-span reinforced concrete culvert spans carries a road over a lake divided by the fill that carries the now-abandoned right-of-way of a railroad. The wide culvert spans beneath roadway and the railroad embankment. The embankment is carried over the roadway by a concrete arch tunnel. The culvert spans 40' and measures 300' wide along the skew (tunnel not included in the survey; the structure number refers to the 2-cell culvert). No alterations to the span were noted.

Historical and Technological Significance: The 2-cell concrete culvert, constructed in 1910, is not individually distinguished. It is significant because it was built, along with the concrete arch spanning above it to carry the railroad over the roadway, as part of the construction of the New Jersey Cut-Off of the Delaware, Lackawanna & Western RR. The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties from Slateford, Pennsylvania to the DL&W mainline near Lake Hopatcong. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

November 12, 2002

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the old 1851 Warren Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152, and 1911155 in Sussex County). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams (1900C18).

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) in Knowlton Township and the Paulins Kill Viaduct (Milepoint 70.63, near Hainesburg in Knowlton Township). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through (viaduct not included in the bridge survey because no roadway is associated with it). It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that

contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

The viaduct is also individually eligible, in and of itself, including superstructure, substructure, and right-of-way over the water feature and highways.

SETTING / CONTEXT The bridge carries a 1-lane 2-way collector road over a small stream surrounded by wooded undeveloped land. The bridge is about 50' from the intersection with US 206. The structures in the area along US 206 are both residential and commercial, and they date from the late 1800s through the 1970s.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 7/9/90, Letter 6/30/95.

SUMMARY The single-span Pratt pony truss bridge is supported by concrete abutments. The deck is laminated timber, and the curbs are timber. The original metal pipe railings remain along the face of the trusses. The lower chord is dented at one location, and welded spacers were added at the bottom chord. The bridge is significant because it is a well-preserved example of a pony truss constructed by a local contractor. It is scheduled to be removed and placed at the county fairgrounds.

SETTING / CONTEXT The bridge carries a 2-lane road and a sidewalk over a small river and Conrail. This line was part of the Lehigh and Hudson River and New York, Susquehanna and Western Railroads before being transferred to Conrail. Just south of the span, the line links with a branch that served the New Jersey Zinc Mine in Ogdensburg, which was an important source of revenue for the L&H. The span is located in a wooded area of homes dating from the 1930s to the 1960s.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 14-span riveted thru girder with floorbeams viaduct is supported on concrete abutments and riveted steel pier bents. A few pier bents were replaced in kind but have welded connections. The girder web in span 2 has welded repair plates. Metal picket railing flanks the cantilevered sidewalk at the north, and modern 3-rail railing flanks the south side. The viaduct span is an example of a common type, and it is neither technologically innovative nor historically distinguished.

INFOR MATION

Bibliography:
H. Leedom Lefforts, Jr., and David Peifer. Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. Washington, DC: Heritage Conservation and Recreation Service, 1979.
Sussex County Engineer. Bridge Files.

Physical Description: The 14-span bridge built on a skew carries a two-lane highway over a single railroad track and the Wallkill River. The bridge consists of from east to west one steel stringer span, one thru girder with floor beams span, three deck girder with floor beams spans, two thru girder with floor beams spans (the first over the railroad track), two stringer spans, and five deck girder with floor beams spans (the first over the river). The bridge is supported by steel pier bents with cross bracing and by concrete spill-thru abutments. The viaduct has a cantilevered sidewalk with metal railing to the north. The structure exhibits no unusual or distinctive construction details.

Historical and Technological Significance: The 14-span viaduct, constructed in 1927, is composed of a combination of thru girder, deck girder, and steel stringer spans, all standard early 20th century bridge types. Although the bridge is a multi-span railroad overpass composed of several very common and well represented bridge types, it is not a technologically distinguished example, and it demonstrates no innovative construction techniques.

The bridge, sometimes referred to as the Franklin Viaduct, is located at the Franklin junction of the former New York, Susquehanna and Western (NYS&W) Railroad's Sussex Branch, the Lehigh and Hudson (L&H) Railroad's main line, and the Delaware, Lackawanna and Western Railroad's Sussex Branch. The railroad right-of-ways were developed from 1860 to 1885 and served to transport through traffic and products of local farms, mines and factories. The bridge was constructed in 1927 to carry an existing county road over the busy rail junction and the river. The setting is undistinguished and does not maintain its historic integrity. Most of the railroad-related structures have been removed, and the rail lines are no longer operable north of Franklin. A short portion of the former L&H and NYS&W tracks are maintained by Conrail as a lightly used branch line.

Lefferts, H. Leedom Jr., and Piefer, David R., Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. 1979.

Physical Description: The skewed reinforced concrete elliptical deck arch bridge with a high rise is flanked by high concrete balustrades with an oval piercing pattern. The date of construction, 1911, is inscribed in the fascia. The well-proportioned span appears unaltered.

Historical and Technological Significance: The deck arch bridge constructed in 1911, is not individually distinguished, but it is significant because it was built as part of the construction of the New Jersey Cut-Off of the Delaware, Lackawanna & Western RR. The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey. The decision to exclusively use reinforced concrete for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The railroad's use of reinforced concrete for all of the structures built along the road did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad. The right-of-way of the New Jersey Cut-Off and the reinforced concrete structures along it are an important part of the history of transportation in northwestern New Jersey.

The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. The DL&W began to acquire other rail lines like the Syracuse, Binghamton & New York RR and the Utica, Chenango & Susquehanna RR, and thus extending their operations to the north and east. Often these acquisitions required the development of new right-of-ways like the Valley and Greene Railroads to connect newly acquired lines with existing DL&W trackage.

In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson Counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken on the Hudson River to Phillipsburg on the Delaware River. Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole, though some of the divisions would lose business (All background information gathered from Taber, 1977).

November 12, 2002

In seeking a more efficient, less circuitous route across western New Jersey to replace the former Warren Railroad right-of-way, the DL&W considered three plans (Taber and Taber, 1980:34-36). The plan chosen was that of what we know as the New Jersey Cut-off, a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. Eleven deck arches were built in New Jersey, all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the bridges are very similar structures. A three-span deck arch bridge was built in Pennsylvania at Slateford, near the junction of the cut-off with the old line.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line. Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the multi-span viaducts, open spandrel arch bridges that spanned valleys and crossed larger water courses. Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. The length and number of spans increased to create massive structures that dominated the landscape.

The Delaware River Viaduct at Slateford, Pennsylvania, spans the river as well as the highways following the river on each side. It is 1,450 feet long and carries trains 65 feet above the water. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The longest spans are those which span the river, five of which are 150 feet at the springing line.

The Paulins Kill Viaduct in Hainesburg, New Jersey is slightly shorter than the Delaware River Bridge, being only 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. This seven span structure had five spans of 120 feet and two of 100 feet. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, built less than five years later on a similar project, the Nicholson Cut-Off.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 7/16/1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

In addition to its engineering significance, the right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

Boundary Description and Justification: The significance of this structure is based on its historic association and physical connection with a right-of-way that is both historically and technologically important. The boundary is limited to the 28.5 mile long right-of-way of the DL&W's New Jersey Cut-Off.

SETTING / CONTEXT The bridge carries a narrow 2-lane county road over the abandoned NJ Cutoff r-o-w in a wooded undeveloped area with a residential neighborhood of single-family homes dating from the early 1900s to the 1950s on one side of the span. The abandoned Greendell concrete railroad station is about 150' east of the bridge. The NJ Cutoff was a significant engineering achievement which was constructed with major cuts and fills, and avoided creating any highway railroad grade crossings along its 28.45 mile length.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94, Letter 03/12/01.

SUMMARY The skewed single-span concrete arch bridge supported on a concrete substructure is flanked by high concrete balustrades. One of over 17 arch spans on the NJ portion of the route, the bridge is a good example of its type, and is historically significant because it is associated with the construction of the 1908-11 NJ Cutoff of the DL&W RR. The cutoff is a technologically significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The bridge is not individually eligible for listing in the National Register of Historic Places but is eligible as a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District under Criteria A and C.

Physical Description: The reinforced concrete deck arch bridge spans 103' and carries an 18' road. The abandoned Greendell concrete railroad station (not included in the survey but observed as a potentially historic resource) is located about 150' east of the bridge. No plans for the span were located but it appears unaltered. The fascia is inscribed with the date of construction, 1911.

Historical and Technological Significance: The 1911 deck arch bridge is not individually distinguished, but it is significant because it was built as part of the original construction of the New Jersey Cut-Off of the Delaware, Lackawanna & Western RR. The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties from Slateford, Pennsylvania to the DL&W mainline near Lake Hopatcong. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new

DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the old 1851 Warren Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152, and 1911155 in Sussex County). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams (1900C18).

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) in Knowlton Township and the Paulins Kill Viaduct (Milepoint 70.63, near Hainesburg in Knowlton Township). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through (viaduct not included in the bridge survey because no roadway is associated with it). It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

SETTING / CONTEXT The bridge carries a 1-lane of a 2-way road over a mill race. The bridge was built as part of the 1921-1931 expansion of the Wheatsworth Co. biscuit factory. Owner F. H. Bennett constructed fanciful medieval concrete factory buildings and the Gingerbread Castle amusement park to attract tourists. The factory ceased operations in the 1970s but portions are still operated as an amusement park. The site, which is well-preserved, appears to be a potential NR historic district.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Wheatsworth Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 2-span encased stringer bridge set on a concrete substructure is flanked on one side with a metal railing with medieval-style posts and on the other side by a concrete balustrade. Original plans for the bridge were not located, but it appears to be stylistically and structurally associated with the 1920s expansion of the Wheatsworth factory. The bridge is not individually eligible, but would be a contributing element to the Wheatsworth Historic District, if it were determined NR eligible under Criteria A and C.

INFOR MATION

Bibliography:
Sussex County Engineer. Bridge Files.
Sussex County Library. "Gingerbread Castle." Vertical Files.

Physical Description: The skewed two-span 33'-long encased stringer bridge rests on concrete abutments and pier. The abutments form part of the retaining walls of the mill tail race. The bridge has two-high pipe railings set between concrete posts with bold paling caps on the downstream side opposite the mill and a simply detailed concrete balustrade with a rectangular pattern on the side adjacent the mill. The structure appears unaltered.

Historical and Technological Significance: The encased stringer bridge is historically associated with a former factory site and amusement park of the Wheatsworth Company. The entire site appears to be a potentially eligible historic site (Criterion A and C). The factory that produced whole-grain flour for biscuits is notable for its masonry and reinforced-concrete construction that includes fanciful medieval-style architectonic features such as asymmetrical windows and doors, balconies, and rounded arches. Adjacent the multi-story factory buildings is a reinforced-concrete construction fairy-tale Gingerbread Castle built by the owners of the mill as an amusement park for children and tourists. The amusement park features several other fanciful masonry and reinforced-concrete buildings and a small lake on the opposite side of Gingerbread Castle Road. The factory and amusement park are technologically significant illustrations of with the moldable qualities of reinforced-concrete in construction of a variety of building types. Gate posts have ceramic tile mosaics illustrating activities that once occurred at the mill. The factory and park appear to constitute a potential National Register historic site, and the bridge because it matches in style and dates to a significant period of the factory's and park's development would be a contributing element. The bridge spans the mill tail race adjacent to the factory building. The span is not individually significant.

In 1921 Wheatsworth Co. owner F. H. Bennett purchased the factory and expanded operations. Industrial activity at the site dated back to the mid-18th century when the Sharp family established an iron forge around which grew the village of Hamburg. In the mid-19th-century the site was used as a distillery and later as a lime kiln. Bennett incorporated a surviving stone mill building in his factory design, but little other physical evidence of earlier industrial activities is visible at the site. The Wheatsworth Company operated the factory from 1921 to 1931 and in the late 1920s began construction of the Gingerbread Castle as a tourist attraction and whimsical tribute to popular children's fairy tales. The amusement's construction coincided with improvements to the State Highway system that were attracting increasing numbers of automobile vacationers to the region. The factory property borders NJ Route 23. In 1931 the factory was sold to the National Biscuit Company, and in 1943 the Plastoid Corporation purchased the facility. Factory operations ceased in 1978, but the amusement park continues to be open to the public. The site retains a high degree of integrity.

Boundary Description and Justification: The bridge is not individually significant, but it is significant for its association with the Wheatsworth Co. factory and Gingerbread Castle amusement park. If the historic site were determined a National Register eligible property, the bridge would be within the boundaries of the eligible property and it would be a contributing resource.

SETTING / CONTEXT The bridge carries a one-lane of a two-directional road in a wooded area over the abandoned New Jersey Cutoff of the Delaware Lackawanna & Western Railroad. The NJ Cutoff was constructed to improve transporting anthracite coal from eastern Pennsylvania to markets east. A significant engineering achievement, the line was constructed with major cuts and fills, and avoided creating any highway railroad grade crossings along its 28.45 mile length.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94 05/05/94, Letter 03/12/01.

SUMMARY The deck arch bridge supported on scored concrete abutments is flanked by standard design concrete balustrades. Both approaches to the bridge are on a horizontal curve. The bridge is significant because it is one of the original reinforced concrete bridges built as part of the 1908-11 New Jersey Cutoff of the DL&W RR, a technologically significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The bridge is individually eligible for listing in the National Register of Historic Places under Criterion C, and is a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District under Criteria A and C.

INFOR MATION

Physical Description: The reinforced concrete elliptical arch bridge spans 85' and carries a 17.7' wide county road. The arch with a high rise extends from a scored concrete substructure, and the road is flanked by standard-design concrete balustrades. The span appears unaltered. The date of construction, 1911, is inscribed in the fascia.

Historical and Technological Significance: The elliptical arch bridge, constructed in 1911, is not individually eligible, but it is significant because it was built as part of the construction of the New Jersey Cut-Off of the Delaware, Lackawanna & Western RR.

The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties from Slateford, Pennsylvania to the DL&W mainline near Lake Hopatcong. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

November 12, 2002

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the old 1851 Warren Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152, and 1911155 in Sussex County). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams (1900C18).

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) in Knowlton Township and the Paulins Kill Viaduct (Milepoint 70.63, near Hainesburg in Knowlton Township). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through (viaduct not included in the bridge survey because no roadway is associated with it). It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of

the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

TYPE STRINGER **DESIGN** PARTIALLY ENCASED **MATERIAL** Steel

 # SPANS 1 **LENGTH** 22 ft **WIDTH** 15.7 ft

CONSTRUCTION DT 1920 **ALTERATION DT** 1980ca **SOURCE** NJDOT

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 1-lane, 2-way road over a small stream in a wooded, sparsely developed area. A late 19th century house is located contiguous to the bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The stringer bridge supported on a concrete substructure is flanked by guide railing placed in circa 1980. The underside of the deck is flush with the stringer bottom flanges so that the stringers are almost entirely encased. Tie rods are anchored through the fascia stringers, which are not encased. The span is neither technologically nor historically distinguished.

TOWNSHIP SANDYSTON TOWNSHIP

TYPE PONY TRUSS **DESIGN** PRATT **MATERIAL** Metal

 # SPANS 1 **LENGTH** 46 ft **WIDTH** 11.6 ft

CONSTRUCTION DT 1890ca **ALTERATION DT** **SOURCE** STYLE

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 1-lane, 2-way street over a shallow stream in a wooded undeveloped area located within the Flat Brook-Roy Wildlife Management Area.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The pin-connected Pratt pony truss bridge supported on concrete abutments has a laminated timber deck. Alterations are limited to the addition of welded outriggers and steel railings were welded to the truss. The span is distinguished because it is a very well-preserved example of an important early metal truss bridge type. Located within undeveloped parkland, the integrity of the original setting has not been compromised. Date of construction and builder are undocumented.

INFOR MATION

Bibliography:
Sussex County Engineer's Office. Bridge Files.

Physical Description: The single-span pin-connected half-hip Pratt pony truss bridge supported on concrete abutments, spans 46' and carries an 11'6" wide road. The four-panel truss is composed of standard-design members. Upper chords are back-to-back channels with cover plate on the top and lattice on the bottom of the built-up box member. Bottom chords are pairs of rectangular section eye bar at center bays and circular section bars at end bays. Verticals are back-to-back angles joined by lattice. Diagonal members are pairs of square section bars, and counters are single circular section rods. Outriggers were welded to the truss at each panel point at unknown dates, and a steel channel guide rail has been was welded to each inside truss face. The span has a laminated timber deck.

Historical and Technological Significance: The ca. 1890 Pratt pony truss bridge is a very well-preserved example of an increasingly uncommon bridge type (Criterion C). The span, although undocumented to date of construction and builder, is a virtually unaltered example of the most common late-19th century bridge type. It is one of four eligible pony truss spans in Sussex County (1900D07, Smith Mill Road, Frankford Twp.; 1900E10, Scott Road, Franklin Borough; 1900W06, Main Street, Walpack Township). The bridge is located within the undeveloped Flat Brook-Roy Wildlife Management Area, and the integrity of setting has not been compromised.

Through the third quarter of the 19th century, a variety of truss designs were developed and patented, but the one that proved to be the most economical, efficient, and easy to fabricate and erect in the field was the Pratt truss, which has the verticals in compression and the diagonals in tension. The truss was patented by Thomas and Caleb Pratt in 1844, and the earliest examples were a combination of wood (for the compression members) and iron (for tensile members). The Pratt truss went on through the century to become the most common design, and it was not until technological advances made it possible to execute reliable field riveted connections after about 1890 that the Warren truss superseded the pin-connected Pratts on the nations highways and byways.

Boundary Description and Justification: The bridge is rated individually eligible. The boundary is limited to the superstructure and substructure of the bridge itself.

CONSULT DOCUMENTS SHPO Finding 4/20/93

SUMMARY The pin-connected Pratt pony truss bridge is supported on stone abutments. In 1938 the superstructure was raised by adding concrete caps to the abutments. The deck is asphalt filled metal deck pans. New members were added at the bottom chords, diagonals and counters. Repairs were welded and many new gusset plates were added. One of over 6 pony truss bridges in the county, alterations have compromised the design integrity. More complete examples of the type are represented in the county.

INFOR MATION

Bibliography:
Sussex County Engineers Office files.

Physical Description: The pin-connected 4-panel Pratt pony truss bridge supported on stone abutments spans 52' and carries a 13'-6" wide road. The superstructure was raised in 1938 by adding concrete capping to the stone abutments. The upper chord members are back-to-back channels with a top cover plate and batten plates at the bottom. Vertical members are built-up I-sections composed of 2 pairs of angles separated by lacing. The lower chords and diagonal members are pair of rectangular section bars. The trusses have been significantly altered. Gusset plates were welded at each upper and lower panel point. New diagonal and lower chord members were welded to gusset plates to supplement the original members. Outriggers were added at each panel point. The floor system was replaced with asphalt-filled metal deck pans.

Historical and Technological Significance: The ca. 1890 pony truss bridge is an altered example of a type that is represented by less altered and more distinguished spans in the county. The alterations have compromised the visual integrity of the span. More complete examples of pin-connected pony trusses in the county are Main Street over Big Flat Brook, 1900W06, in Walpack Center historic district; Smithhill Road over Branch of Paulins Kill Lake, 1900D07, in Frankford Township; and Scott Road over Wallkill River, 1900E10, in Franklin Borough.

CONSULT DOCUMENTS SHPO Letter 3/12/01

SUMMARY The pin-connected Pratt pony truss bridge is supported on ashlar abutments. In 1944 the trusses were strengthened with the addition of welded plates to the vertical, diagonal, and lower chords. Outriggers were added, and channel sections were welded to the floor beams. The span is one of the few documented truss spans in the county, and it was fabricated by a notable company. The bridge was constructed within the period of significance of the district, and it is a contributing element under Criterion C.

INFOR MATION

Bibliography: Pamela Thurber, "The Groton Iron Bridge Company," Historic Ithaca & Tompkins, NY, Newsletter Fall 1983, New Series Vol. 1,2, pp. 1-4.
Office of New Jersey Heritage. Sussex County, Walpack File.

Physical Description: The pin-connected Pratt pony truss bridge supported on ashlar abutments spans 70' and carries an 11'-6" width roadway. The truss members are standard sections, and they have been strengthened with welded plates. Outriggers were added to the trusses, and channel sections were welded to the floor beams. The deck was replaced with a metal grate deck. The dates of the alterations to the span are not documented. No plans for the bridge were located.

Technological and Historical Significance: The Pratt pony truss bridge, located in the Walpack Center Historic District, was constructed in 1889 by the Groton Bridge & Manufacturing Co., as is documented on a plaque located on top of one of the trusses. The bridge is significant because it is a documented example of an uncommon bridge type constructed by a noted bridge manufacturer. It was built within the period of significance of the district, and it is a contributing element (Criteria A & C).

The Groton Bridge & Manufacturing Company, of Groton, New York, was formed in 1877 under the name of the Groton Iron Bridge Company. The company was formed as the result of a merger between the Groton Iron Works, a blacksmith shop owned by Charles and Lyman Perrigo, and the Groton Separator Works, a manufactory of agricultural equipment owned by Daniel Spencer and Frederick Avery. It became a major bridge manufacturer primarily constructing small Pratt truss bridges in New York State. The firm was run by Ellery Colby and Frederick Avery during its first ten years of operation. Colby was a significant figure in New York State bridge building who later formed the Owego Bridge Company. In 1887, the name of the firm was changed to the Groton Bridge and Manufacturing Company, and it expanded operations. During this period, the company constructed many spans throughout the nation, the largest being an eleven-span bridge in Little Rock, Arkansas in 1896, and a multi-span crossing of the Anacostia River at Pennsylvania Avenue in Washington, D.C. in 1890 (replaced in 1936 by the John Phillip Sousa Bridge). In 1899, the firm became part of the American Bridge Company, and continued operation, primarily in New York State, until it folded in 1920.

The Walpack Center Historic District is an example of one of the first forms of urbanism in the country, the rural service center. Rural service centers thrived from the mid-nineteenth century through the early twentieth century, providing a marketplace for the local agricultural industry. Walpack Center was geographically isolated, located in a valley between two ridges of the Kittatinny Mountains. The geography of the area dictated a need for a local marketplace because travel was difficult. The farmers in the area depended on the local market to sell their goods, and the local people depended on it to obtain goods. With the advent of the automobile, travel became easier and this interdependence no longer existed. The town did not expand with increased transportation, as other service centers did, because of its isolated location. Building in the town came to almost a complete end in the early 1900s, and the town retains much of its late 18th century character. The architecture is not sophisticated, but rather ordinary, reflecting the lifestyle of the rural town during its peak. The bridge is located at the edge of town within the historic district, and it was constructed in 1889, during the period of significance.

Boundary Description and Justification: The bridge is an eligible contributing resource to the National Register-listed Walpack Center Historic District (1980). The bridge is completely within the boundaries of the historic district delineated in the nomination (refer to NR Sussex Co. File at HPO). The eligible resource includes the bridge as well as its surroundings.

SETTING / CONTEXT The bridge carries a 2-lane highway with shoulders over a small stream in a wooded residential area dating from the early 1900s to the 1920s. The bridge is skewed beneath a concrete arch tunnel, 1911155, built at the same time to carry the r-o-w of the DL&W RR NJ Cutoff (abandoned) at the Pequest Fill. The cutoff is a significant engineering achievement noted for its concrete structures, large cuts and fills, and avoided creating any highway railroad grade crossings along its 28.45 mile length.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94, Letter 03/12/01.

SUMMARY The 2-span concrete culvert supported on a concrete substructure is part of a 2-tier structure, and it spans on a skew beneath the concrete arch tunnel (1911155) that was constructed at the same time. Individually the culvert is not distinguished, however, it is one of the original concrete structures built as part of the 1908-1911 NJ Cutoff, a technologically significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The structure is not individually eligible for listing in the National Register of Historic Places but is eligible as a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District under Criteria A and C.

INFORMATION

Lefferts, H. Leedom Jr., and Piefer, David R., Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. 1979.

Physical Description: The 2-span reinforced concrete culvert spans beneath a concrete arch tunnel (1911155) that carries abandoned RR r-o-w over the road. The culvert is inscribed with the date of construction, 1910, on the fascia. The span exhibits typical construction and appears unaltered.

Historical and Technological Significance: The concrete culvert, constructed in 1910, is not individually distinguished, but it is significant because it was built, along with the concrete arch tunnel that spans above it, as part of the construction of the New Jersey Cut-Off of the Delaware, Lackawanna, & Western RR. The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties from Slateford, Pennsylvania to the DL&W mainline near Lake Hopatcong. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the old 1851 Warren Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152, and 1911155 in Sussex County). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams (1900C18).

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) in Knowlton Township and the Paulins Kill Viaduct (Milepoint 70.63, near Hainesburg in Knowlton Township). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through (viaduct not included in the bridge survey because no roadway is associated with it). It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of

the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

SETTING / CONTEXT The bridge carries the abandoned DL&W RR NJ Cutoff over US 206 and a minor stream in a wooded residential area dating from the early 1900s to the 1920s. It is part of a 2-tier arrangement with the highway crossing the stream on 1911154. The Cutoff is an historically important route that was constructed to improve moving anthracite coal from Pennsylvania to markets east. Also a significant engineering achievement, the line was constructed with major cuts and fills, and avoided creating any highway railroad grade crossings along its 28.45 mile length.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94, Letter 03/12/01.

SUMMARY The concrete arch tunnel supported on a concrete substructure spans over 1911154. The high embankment over the tunnel was originally part of the Pequest Fill. Guide rail has been placed at the approaches. The span, 1 of 7 in the county built as part of the 1908-1911 NJ Cutoff. It is a technologically significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The structure is not individually eligible for listing in the National Register of Historic Places but is eligible as a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District under Criteria A and C.

CONSTRUCTION DT 1927 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT BAUER(UNION) & HOPKINS(MORRIS) **BUILDER** HENRY E. TERRILL

SETTING / CONTEXT The bridge is located in a wooded area along the Passaic River, which at this location is the boundary between Union and Morris Counties. A late-20th century water treatment plant is located along the river nearby. The bridge carries 2 lanes and two sidewalks over the river.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stringer bridge rests on concrete abutments and pier. The round-nose pier and the wingwalls are rusticated. The stringers are completely encased in concrete, and the fascia is paneled. The concrete parapet is also paneled, and the posts at the center of the bridge have plaques from the two counties. The bridge is not technologically or historically distinguished. It is one of over 25 remaining stringer bridges in Union County built before World War II.

SETTING / CONTEXT The long viaduct carries 4 lanes of divided traffic over a meandering river and local streets in an late-19th century brick and frame row houses, cleared land, and commercial blocks in a mixed-use section of Elizabeth. The buildings have been altered, and the area does not appear to have historic district potential. The viaduct is later than the surrounding buildings, and, because of its size and age, is an intrusive element in the neighborhood.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 9/11/91, Letter 6/30/95.

SUMMARY Built as part of the NJ 25 metropolitan traffic plan designed by the Department in response to the opening of the Holland Tunnel, the 42-span viaduct composed of reinforced concrete and steel multi-girder spans is historically and technologically significant. The reinforced concrete girders are not a commonly used bridge type in the state, and historically the span represents a major structure built by the Department to resolve the efficient flow of thru traffic through an urban area.

S. Johannesson. "Viaduct Design and Structure," Engineering News-Record, Vol. 100, No. 1, (Jan. 5, 1928), pp. 5-8.

Physical Description: The 1,852-foot long, 42-span viaduct is composed of reinforced concrete multi-girder, encased steel thru girder, and encased deck multi-girder spans. It was built with a vertical clearance of 22' over mean high water. The whole is finished with standard-design concrete balustrades enclosing the cantilevered safety walks on each side of the 48.5-foot roadway. The elevated viaduct that crosses three city street and the meandering Elizabeth River three times is accessed by a 325' approach ramp on the south end and a 470' ramp on the north end. Because the structure crosses six features, it is made up of skewed and 90 degree crossings with steel girders at the feature crossings linked by two- or three-span continuous reinforced concrete deck multi-girder and floor beam spans. The earth-filled ramps have concrete retaining walls and are finished with the same balustrade as the viaduct itself. The ramps are flanked by surface local roads.

The northerly end of the viaduct over Elizabeth Avenue is a 90-degree crossing composed of three span continuous haunched concrete encased deck multi girders. The five girders with a floor beam and stringer flooring system bear on shoes on concrete abutments or bents. The three crossing spans to the south are encased steel deck multi-girders at various skews. They are supported on reinforced concrete columns with bracketed struts. The southerly terminus of the viaduct that crosses the Elizabeth River and paralleling Pearl Street is composed of four encased skewed thru girders supported on concrete columns and a concrete abutment at the south approach ramp. The approach spans are primarily 90-degree two-span continuous reinforced concrete deck multi-girders with cantilevered end sections. They have a haunched profile and are supported on concrete columns with decorative corner brackets. The design with flexible twin columns, set 2' or 3' apart and joined at their bases, and the cantilevered sections at all expansion points to ensure that the joints do not bind and that the joints develop elastic movements only. When adjacent to a skewed crossing span, a third span is used on one face to compensate for the skew. This results in the skew being compensated for in the end spans only. A concrete deck which is integral with the floor beams and stringers is used throughout. The viaduct appears to survive unaltered.

Historical and Technological Significance: The Elizabeth River Viaduct was designed and built the New Jersey State Highway Department as part of the historically and technologically significant Route 1 Extension, the approximately 13-mile long arterial highway from the end of the 1927 Holland Tunnel to Bayway Circle on the south side of Elizabeth. Considered to be America's first "super highway," the carefully considered and designed roadway is distinguished by a variety of innovative engineering solutions to carrying a wide, limited access, high-speed highway through congested areas and some difficult terrain. The portion of the highway between the tunnel toll plaza and what was Airport Circle on the north side of Newark is carried under and over Jersey City (Hudson County) streets and water features on a variety of distinguished bridges and viaducts, including in the spectacular Pulaski Skyway cantilevered thru truss spans over the Passaic and Hackensack rivers. That approximately 7.25 mile-long section of the route, which is predominantly open cut through the Bergen Hill or elevated viaduct, is not of traditional design, and it is technologically and historically significant.

Southerly of Airport Circle the highway was planned as a surface road with some grade crossings. The 1,852'-long, 1929 Elizabeth River Viaduct, which crosses three city streets and an S-curve in the river, is the most significant original structure associated with the Route 1 Extension south of Airport Circle because of its size, design, and state of preservation. The structure employs the same distinctive engineering solutions, like the flexible twin column bents for the reinforced concrete approaches and the concrete railings and curbs, as the elevated portion of the important roadway. Beyond its common history with the other structures on the Route 1 Extension, the viaduct is technologically significant as an engineering solution to a specific transportation problem. It reflects thinking on economics of travel and construction and long-term maintenance and structure performance. While not innovative technology, the complex structure does reflect

A. G. Lichtenstein & Associates, Inc. performed initial survery.

Correction Updates Etc should be sent to
Correspondence.Unit@DOT.State.NJ.US
November 12, 2002

then-current engineering concepts, and the approaches are a design not common in the state (criteria A, C).

The final design of the viaduct and the other structures on the route was based on the decision to use encased steel whenever possible. "Complete designs were made of a number of types of viaduct structures, both of concrete and of steel with a concrete or cement-mortar protection, with various span lengths. Comparative estimates of cost indicated that if the subsurface conditions were good and the span lengths uniform, a reinforced-concrete structure with a moderate span length (say up to 40ft.) would be economical. If, however, the subsurface conditions were such that greater span lengths were advisable, or if the surface conditions required a longer or skew spans of varying lengths, a steel structure of simple supported girders or trusses was indicated as the more economical" (Johannesson, "Viaduct Design ... ," p. 6). Because much of Route 1 Extension passed through developed areas with existing street and railroad patterns, it was only at certain places, like the Elizabeth River Viaduct, that it possible to use reinforced concrete structures. Additionally, "no attempt was made to distort the alignment for the purpose of improving the angle of a crossing over highways, railroads, and rivers, because any saving in construction would have been overbalanced greatly by the consequent additional cost of vehicle operation" (Johannesson, "Lincoln Highway ...," p. 1392). Thus the design of the viaduct reflects the thinking and decision making that went into the design of one of the most important, early vehicular transportation routes in the country.

The Route 1 Extension, or Route 25 as it was later designated, was designed by the New Jersey State Highway Department, William G. Sloan, State Highway Engineer. Morris Goodkind was the State Bridge Engineer, and the design engineer for the project was Sivgald Johannesson, who later became the head of the planning section of the Department.

Boundary Description and Justification: Although the viaduct was built as one component of a historically significant road development campaign, only the north approximately 7.25 miles of the highway are evaluated as a potential historic district. Most of the southern portion of the highway as a whole has lost its integrity of original design and never was technologically significant. The viaduct, however, is technologically significant based on its design and integrity of original design. The significant boundary is limited to the substructure and superstructure of the elevated portion of the 1,852-foot long, 42-span structure and the earth-filled approach ramps at either end. The mixed-use late-19th and early-20th century neighborhood surrounding the structure in Elizabeth does not possess historic district potential.

SETTING / CONTEXT The bridge carries one active railroad track over a divided highway in an urban area in Elizabeth. The freight line was built by the CNJ RR in 1915. It was widened to accommodate development and improvement of the Route 1 Extension, the 1925-32 approach road for the Holland Tunnel that was developed by the state 1925-1932. The road is the prototype of the "superhighway" in this country. The highway is at grade in this section. It is elevated in Hudson County.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Historic District Status Unresolved.

CONSULT DOCUMENTS SHPO Finding 9/11/91, Letter 6/30/95.

SUMMARY The bridge has been so compromised by subsequent changes that it no longer characterizes the ca. 1930 building campaign for the "superhighway." The removal of the majority of the superstructure and the modifications to the substructure in 1987 have altered the visual integrity of the original bridge. In addition, the recent changes to the US 1&9 roadway and the isolation of this element from the other structures of the historic route was an important aspect of it being undistinguished.

SETTING / CONTEXT The viaduct carries a local street over a divided highway in a mixed use area of Elizabeth. The viaduct was built after the 1925-1932 completion of the Route 1 Extension approach road to the Holland Tunnel, but it was apparently part of the conceptual plan for the route.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 9/11/91, Letter 6/30/95.

SUMMARY The overpass that consists of encased stringers and reinforced concrete T beam spans has no elements that would be considered unusual or innovative. It was, however, determined by the SHPO to "be a self-contained, ornamented, relatively intact viaduct which may be associated with public sponsorship and typical of highway viaducts of the period." The structure has a high level of integrity with the only alterations being removal of the asphalt paving block wearing surface and the added fence.

CONSULT DOCUMENTS SHPO Finding 02/08/90

SUMMARY The superstructure of the two-span stringer bridge is being completely replaced with prestressed concrete box beams. The original concrete substructure remains, with new concrete caps on top of the pier and abutments. The new structure will have stone parapets. The bridge has not retained the integrity of its original design. The original structure was a common bridge type that was evaluated as not eligible, and the new bridge is not old enough to be evaluated as historically significant.

DESIGNER/PATENT JACOB L.BAUER, COUNTY ENGINEER **BUILDER** AMERICAN.BRIDGE, DVR.BLR.WRKS

SETTING / CONTEXT The bridge is located in a potential large historic district of early-20th century residences. The bridge carries a two-lane street and two sidewalks over the Rahway River, a winding waterway that is bounded by parklands for much of its length. The homes in the district are well-preserved examples of picturesque and academic Colonial Revival styles. Bridges 2003014, 2003072, both thru-girder spans, and 2003025, a reinforced concrete arch, are also located in the potential district.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Agreed Potential Cranford Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span thru-girder bridge sits on concrete abutments. The rolled floorbeams are encased except for the bottom flanges. The cantilevered sidewalks are enclosed with fence-like metal railings. The bridge is a representative example of a common early-20th century bridge type, and is not technologically or historically distinguished by itself. It is significant because it was constructed during the period of significance of the potential district.

DESIGNER/PATENT JACOB L.BAUER, COUNTY ENGINEER **BUILDER** LOGAN CONSTRUCTION CO.

SETTING / CONTEXT The bridge is located on a main street in Cranford, and it carries two lanes and two sidewalks over the Rahway River. The neighborhood is dominated by well-preserved, architecturally significant early-20th century picturesque and academic Colonial Revival dwellings. The neighborhood has historic district potential. Two other thru-girder bridges contribute to the potential district, and one reinforced concrete arch bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Agreed Potential Cranford Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span thru-girder bridge is supported by concrete abutments with wingwalls. The rolled floorbeams are encased except for the bottom flanges. The cantilevered sidewalks have reinforced concrete decks and the original iron railings. The bridge deck was replaced in 1979, with a slight crest curve and curbs on the inside face of the girders. Though a representative example of a common bridge type, the bridge is significant as a contributing element to the potential historic district.

SETTING / CONTEXT The bridge is located in Sperry Park, a casually landscaped Union County park that is part of a greenway along the Rahway River. The bridge carries a two-lane, two sidewalk street over the river. The surrounding neighborhood is dominated by post-WW II residences and commercial structures. The park does not have landscape architecture significance.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Union County Park System Multiple Property nomination, May contribute.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single reinforced concrete arch bridge has been rehabilitated with gunite on the fascias as well as the intrados. The repairs do not detract from the structural integrity. The original metal railings that cross the bridge are flanked at the approaches by concrete parapets. The 1916 bridge is a representative example of a common bridge type from the early-20th century, and is one of 9 pre-World War II deck arches in the county. The bridge is not technologically or historically distinguished.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge carries two lanes and two sidewalks over the Rahway River. A greenway borders the winding river through the county, and this bridge is located next to McConnell Park. The neighborhood surrounding the park and bridge is early-20th century residences predominantly in the picturesque and academic Colonial Revival style. The area has historic district potential. The district includes three other bridges, all thru-girder spans from the period of significance of the district.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Agreed Potential Cranford Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete deck arch bridge has paneled spandrels and wingwalls. The arch creates a vertical crest curve over the bridge, which is skewed. A metal railing is bolted to the curb at the spandrel wall. Though the railing is not original, it is not intrusive into the character of the bridge or its surroundings. The bridge is significant because it was built during the period of significance of a potential historic district but is not technologically distinguished in its own right.

CONSTRUCTION DT 1875 **ALTERATION DT** Demolished **SOURCE** COUNTY ENGINEER
DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge is located in a wooded greenway along the Rahway River with some late-20th century residences nearby. The bridge carries a two-lane street with two sidewalks over the Rahway River downstream from National Register-listed Droescher's Mill. A dam approximately 300' upstream creates a mill pond and adds to the park-like atmosphere of the mill and bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Bridge was Individually Eligible. Potential Union County Park System Multiple Property nomination, May have contributed.
CONSULT DOCUMENTS SHPO Finding 07/18/90, Letter 03/12/01.

SUMMARY The 1875 three-span brick arch bridge no longer carries the load of traffic. A Bailey truss was placed over the arches in 1985 due to the crumbling state of the southern arch. The arches are skewed using a ribbed pattern consisting of approximately 2' wide ribs stepped along the intrados. The arches have a stone fascia, and a metal railing that was placed in 1926. The ribbed brick intrados is a unique feature; the arches are deteriorating. Despite this, the bridge remains individually eligible for listing in the National Register of Historic Places under Criterion C.

INFOR MATION

Bibliography:
Cranford Board of Trade. Cranford, New Jersey. 1913.
County Engineer Office; Bridge File.

Physical Description: The 1875 three-span brick arch has a ribbed intrados. The bricks were laid in a stepped pattern to provide for the skew of the bridge as it crossed the waterway. Each rib is approximately 2' wide, and is stepped 6" from the preceding rib. The spandrel walls are ashlar with a concrete cap. The arches all have gauged ring stones. A concrete footing is present at the base of each arch, with a short buttress protruding from the upstream face of the structure. In 1926, the original metal railing was replaced with another metal railing, each type being finely detailed for this important bridge.

The arch action of the spans has been lost. The ashlar spandrel wall has fallen into the river, as have parts of the brick arches which has caused the bridge to fail.

In 1985, a Bailey truss was placed over the arch structure to carry the vehicular traffic across the river and the deteriorated arch. Additional precautions have been made for pedestrians to cross the bridge in a safe manner, with chain-link fencing and beam guide rails marking sidewalks.

Historical and Technological Significance: The ca. 1875 three-span brick arch bridge with the stepped intrados is a rare example of its design. No other example has been identified on a highway in the state. However, deterioration has cause the arch action of the span to fail. It is evaluated as not eligible due to its loss of structural integrity. The date of construction is based on the style and type, but it has not been documented.

SETTING / CONTEXT The bridge is located in an industrial area that is in the process of being cleared and redeveloped for recreational use. The one-lane bridge crosses a small waterway near its outlet into the Arthur Kill. The waterway is now used only for pleasure craft, as only a few hundred feet of the river are navigable. The bridge provides access to a concrete plant located along the Arthur Kill.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed Strauss heel trunnion bridge has a Warren thru-truss moveable span. The bridge bears on concrete abutments. The concrete counterweight has been repaired several times. The original gearing is housed above the roadway, along with electric motors from 1940. The only operational moveable-span bridge in Union County, the bridge is a well-preserved example of an uncommon type and is historically and technologically noteworthy.

INFOR MATION

Bibliography:
Hool and Kinne. Movable and Long-Span Steel Bridges. 1943.
Union County Engineer. Bridge File: EL1. 1902 Bauer Atlas of Union County.
Waddell, J.A.L. Bridge Engineering. 1925.

Physical Description: The 158'-long single-leaf Strauss heel trunnion bascule bridge has a rivet-connected Warren with verticals moveable span fabricated of traditionally composed members. Because the bridge is skewed, the trusses are different lengths; 131-8" on the west truss, 116'-5" on the east truss. The roadway is 17'-8" wide. The substructure is concrete. The flooring system, which includes an open grate deck, was strengthened in 1976, and the concrete counterweight, carried overhead by a framed truss that pivots on two trunnions when the bridge is in operation, was repaired in 1976. The operating machinery, made up of open gear sets and line shafts, is located in a corrugated metal-clad machinery closure adjacent to the operating strut fitted with a rack and the operating pinion. The controls are located in the small, gable-roofed brick tender's house adjacent to the span. A standard-design metal railing encloses the cantilevered sidewalk. The bridge is well preserved.

Historical and Technological Significance: The 1920 Strauss heel trunnion single-leaf bascule bridge, designed by the Strauss Bascule Bridge Company of Chicago and fabricated by American Bridge Company's Pencoyd plant, is a well-preserved example of a proprietary bridge type that is not common in New Jersey (criterion C). The heel trunnion is a variation on the patented articulated parallel-moving counterweight design Joseph B. Strauss developed in 1905. Unlike the articulated counterweight bridges, in the heel trunnion design the counterweight trunnion is a fixed pivotal point. It is located at the top of a stationary tower supported by the main column and an auxiliary column. The counterweight is carried by one end of a trussed frame. The other end of this trussed frame is connected by a pivot to a link which in turn attaches to the inclined end post of the thru truss superstructure by a pin. This arrangement provides a parallelogram of linkages with the side formed by the triangular counterweight tower with the initially mentioned fixed pivotal point. Near the center of the tower is an "operating strut" with a rack that is pulled by the operating pinion causing the parallelogram to close up thereby opening the leaf. This is one of only two documented road-carrying heel trunnion bridges in New Jersey; NJ 7 over the Passaic River in Bergen County (0208150) is the other. Several more survive on the state's rail lines.

Boundary Description and Justification: The bridge is evaluated as individually significant, and the boundary is limited to the superstructure and substructure of the bridge itself and the tender's house.

SETTING / CONTEXT The bridge is located in an industrial area that is undergoing clearing and redevelopment for recreational use. The bridge carries a 2-lane road over a tidal river. This section of the river is used for recreational marine traffic only.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1908 Strauss overhead articulated counterweight bridge is supported on a concrete substructure. The moveable span is riveted Warren pony trusses, and the concrete counterweight is enclosed by a lattice screen. Although the bridge was fixed in 1984 after the tenders shanty burned, the bridge remains as one of the earliest and most complete patented Strauss overhead counterweight bridges in the state. The bridge is a historically and technologically distinguished structure.

INFOR MATION

Bibliography:
Union County Engineer Office. Bridge File: 2004002.
Waddell, J.A.L. Bridge Engineering. 1925. 1902 Bauer Map of Union County.

Physical Description: The 80'-long single leaf bascule bridge is a Strauss articulated overhead counterweight type supported on a concrete substructure. The lift span is a rivet-connected Warren pony truss span with a 24'-8" roadway. It is traditionally composed of built-up members as are the trunnion columns, tower, and counterweight linkages that permit the counterweight to pivot and move parallel to itself during operation of the bridge. A distinctive detail of the 1907 bridge is the lattice, or lacing as it is identified on the Strauss Bascule and Concrete Bridge Company plans, enclosure of the counterweight that is located 30' above the roadway. The superstructure is remarkably complete. The steel grid deck was installed in 1976 as part of an upgrading of the floor system. The most significant alteration to the bridge is the loss of the operator's shanty and controls as the result of a fire in 1984. The bridge has consequently been fixed in the closed position, but the gear sets and shafts are still in place. Plans for the original mechanical systems are preserved in the County Engineer's office. The original pipe railings and safety gates are still place.

Historical and Technological Significance: The 1908 Strauss overhead articulated counterweight bascule bridge designed by the Strauss Bascule and Concrete Bridge Company of Chicago, Illinois, is one of the earliest and most complete examples of the technologically important bridge type in the state (criterion C). In addition to its early date of construction, this example of what would go on in the early-20th century to become the most popular moveable bridge type in the country is distinguished by the fact that it has an enclosure around the raw concrete counterweight. The metal lattice enclosure or screen was an aesthetic consideration, and the detail has been identified on only one other bridge in New Jersey; the 1906 Federal Street bridge in Camden (043B008). J. B. Strauss (1870-1938) invented the pivoting counterweight linkage used at the South First Street bridge, and he applied for a patent in 1905, the same year the first bridge of this type was built in Cleveland. That year he also founded the Strauss Bascule and Concrete Bridge Company in Chicago to market his bridge designs. Strauss went on to become the most widely respected moveable-span bridge engineer of the pre-World War II era.

Strauss reasoned that if, unlike the traditional trunnion bridge, which operates like a seesaw and moves in a vertical plane on a horizontal steel pivot, the entire weight of the counterweight could be concentrated at the end (tail) of the moveable leaf, it would then be possible to use a lighter counterweight. Such an arrangement also meant a shorter tail end to the leaf, thus saving on materials that the "counterweight could be made in such shape that no pit is required to receive it when the leaf is in the upright position'" (Waddell, p. 704). The patented linkage, or arms, ensures that the counterweight will always move in a series of parallel positions and thus maintain the position of the weight at the tail end of the leaf.

When the Strauss overhead counterweight span at South First Street was erected, it was the first bridge at the crossing. A 1902 county map shows the area next to the industrialized Arthur Kill-Newark Bay waterfront as platted but not developed. The bridge was built just upstream from the South Front Street span. In 1984 a fire destroyed the original operator's house, electric motor that operated the span, and the controls. It was not replaced, and the bridge was fixed in the closed position at that time. A machinery plan for the bridge survives, so how the operating mechanism was arranged is well documented. Despite the loss of the operator's house, the superstructure survives in a remarkably complete state of preservation making this bridge one of the most important of its type in New Jersey. It is one of at least five Strauss overhead counterweight trunnion bridges built between 1907 and 1938 remaining in the state. Others include 043B008, 01M0001, 03H8001, and 1707150.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The significant boundary is thus limited to the substructure and superstructure and the operator's shanty.

SETTING / CONTEXT The bridge is located in a greenway that follows the Robinson's Branch of the Rahway River through a neighborhood of post-World War II residences. The bridge carries four lanes of traffic and two sidewalks over the stream.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes
CONSULT STATUS Individually Eligible. Potential Union County Park System Multiple Property nomination, May contribute.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span brick arch bridge sits on ashlar footings. Concrete repairs were used to buttress the piers and form cutwater piers at the base of the arches. The spandrel walls are rusticated ashlar as are the ringstones. The bridge appears to have been widened in kind by 15'-20' on each side, and the stone parapets moved out with the face of the bridge. The bridge is a significant example of a brick arch bridge, one of four in Union County.

INFOR MATION

Bibliography:
Robinson, E. Atlas of Union County, New Jersey. 1882.
Sanborn Insurance Atlas, Rahway, New Jersey, 1923.

Physical Description: The handsome three-span brick arch bridge rests on ashlar footings with concrete buttressing at the upstream face of the piers. The spandrel walls are ashlar, as are the ringstones. The bridge is 80' in width from the outside faces of the ashlar parapets. Approach guide rails do not cross the bridge or connect to the stone of the parapets. Iron signposts naming Robinson's Branch are present at the approaches to the bridge.

Historical and Technological Significance: The well-preserved ca. 1875 three-span brick arch bridge is a significant example of its type in the region based on its size and state of preservation (criterion C). The brick arch is a bridge type that was used in north New Jersey in the 1870s, 1880s, and early 1890s. No specific information about the date of construction or the builder could be located. The date is based on stylistic comparison with the 1875 Lincoln Avenue bridge (2003006).

On initial field inspection it appeared that the bridge had been widened in-kind at some point, but after researching old atlases and insurance maps, the bridge appears to have been 80' wide since at least 1882. The construction of such a wide bridge signifies the importance of the structure in the transportation system of the city, county, and state. The bridge is well-preserved, and is still very functional in its ability to handle traffic loads imposed on it in the late-20th century. It is the widest of three identified brick arch bridges in Union County.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The significant boundary is limited to the span itself.

CONSULT DOCUMENTS SHPO Letter 6/30/95. DOE 11/30/95.

SUMMARY The 6-panel Warren thru truss span has concrete abutments. The riveted members are built-up from angles, plates and lacing. Struts between the top chords have lattice webs. The bottom chord is encased, as are the stringers and floorbeams. The cantilevered sidewalks retain the original metal railings. One of 5 similar spans built by the CNJ in the vicinity, this one is not as old or interestingly detailed as several of the others. It is not technologically notable. Tuttle Parkway is noteworthy.

SETTING / CONTEXT The bridge is located in a 20th century residential and commercial area. The ca. 1914 brick factory that manufactured Marconi Wireless equipment through the war is adjacent to the bridge. It carries 2 tracks over a 4-lane state route divided by a mountable median. The railroad was developed by the Lehigh Valley Railroad in the late-1880s. The grade crossing was eliminated prior to 1908. The line is used by NJT and Conrail.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Central Railroad of NJ Main Line Corridor. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95. DOE 11/30/95

SUMMARY The three-span deck girder bridge is supported on ashlar piers, one concrete abutment and one ashlar abutment. The deeper end span was placed in 1959. It sits on the concrete abutment and an ashlar pier with a concrete cap. The pier was reduced in height to accommodate the deeper 1959 girders. The existing girders were modified to extend down to the new bearings. Each track is supported by a pair of girders that have lateral K-bracing. The bridge is not historically distinguished.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span stringer bridge is supported on a concrete substructure. The round nose pier and abutments are unadorned, as they rise only a few feet above the water. The encased stringers support the concrete deck. The balustrades with paneled posts are typical of county-designed bridges. The bridge is a representative example of a common bridge type, of which over 25 from the pre-WW II era remain in the county, and it is not technologically or historically distinguished.

SETTING / CONTEXT The bridge is located at the border of Union and Somerset Counties. It carries one lane of one-directional traffic and two cantilevered sidewalks over the stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed one-span thru-girder bridge sits on concrete abutments. The members of the bridge are riveted, built-up beams with the exception of the rolled stringers, which are encased except for the bottom flange. The built-up floorbeams hang from the girders, connecting to each girder's bottom flange. This is an uncommon detail on an otherwise ordinary bridge type. The sidewalks are cantilevered from the girder. The bridge is not technologically or historically distinctive.

CONSTRUCTION DT 1875ca **ALTERATION DT** 1924 **SOURCE** STYLE/PLAQUE

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in downtown Rahway City, surrounded by mid- to late-19th century commercial structures and 20th century multi-unit housing. The bridge is on a two-lane street with parking lanes and sidewalks. It crosses the Robinson Branch of the Rahway River, a waterway that is channeled through the city with rubble stone as well as concrete retaining walls.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The undocumented three-span bridge is a combination of stone and brick arches founded on rusticated ashlar cutwater piers and abutments. The center section of each arch is stone, with 13' of brick arch widening on each side at an unknown date. The spandrels are coursed ashlar with gauged ringstones. In 1924, paneled concrete parapets were added by the county. One of only two stone arch spans in the county (2012150 is other), this bridge is historically and technologically distinguished.

INFORMATION

Bibliography:
Robinson, E. Atlas of Union County, New Jersey. 1882.; Sanborn Insurance Atlas, Rahway, New Jersey, 1886, 1891, 1896, 1901, 1908, 1915, 1923.
1902 Bauer Atlas of Union County.

Physical Description: The three-span arch bridge is a combination of stone and brick arches. The center portion of the bridge is a stone arch structure, approximately 40' wide. On each side of the stone arch is a brick arch approximately 13' wide. The arches are founded on ashlar footings with cutwater pier heads. In 1924, paneled concrete parapets were added to the structure above the ashlar spandrel walls.

The bridge underside is inaccessible from the street as the parapets abut buildings and privacy walls that follow the banks of the river to the edge of the sidewalk. Stone retaining walls line the banks of the river in this densely developed urban setting.

Historical and Technological Significance: The ca. 1875 stone and brick arch bridge is one of the oldest bridges in Rahway, and is one of two stone arch spans in the county. The stone structure dates stylistically to circa 1875. The date of the brick arch extensions is not known, but research of 19th- and early-20th century atlases and maps show the bridge to be 66' wide, its present width, as early as 1882.

Despite the 1924 concrete parapet, the structural integrity of the arches has been maintained, and the bridge ranks as a locally significant example of a bridge technology that is not common in the county (criterion C). The other stone arch bridge, the 1872 Morris Avenue (NJ 82) over the Rahway River (2012150) was determined not eligible by the SHPO in 1985.

Boundary Description and Justification: The bridge is evaluated as individually distinguished, and the significant boundary is limited to the span itself.

CONSULT STATUS Bridge was Not Individually Eligible. Potential Rahway River Park, May have contributed. Potential Union County Park System Multiple Property nomination. May have contributed.
CONSULT DOCUMENTS DOE 10/28/83, SHPO Letter 6/30/95

SUMMARY The Pratt thru-truss bridge with deck girder approach spans was originally a 21' wide riveted center-bearing swing span. It was extensively altered in 1930 when it was widened approximately 5'. The verticals and diagonals were reinforced with welded plates, and the cantilevered sidewalks were added. The bridge was "fixed", and the operating mechanism has been removed. The numerous alterations and inoperable condition make the bridge an undistinguished example of a well-represented bridge type.

INFOR MATION

Union County Engineer. Bridge File: RA23.

Physical Description: The main span of the 3-span bridge is a 158'-7' long, 10-panel Pratt thru truss rim-bearing swing span bridge of riveted construction. The approach spans are rolled section deck girders with floor beams and stringers. The substructure is concrete. The members are traditionally composed with built-up box sections for the top chord and inclined end posts, laced verticals, and diagonals and counters of angles joined by battens. There are numerous welded repairs and reinforcing.

In 1930, the originally 21' out-to-out bridge was widened 5', and most of the members were strengthened by welding steel plates to the existing fabric. The cantilevered sidewalks were also added in the 1930 project. The brackets were welded to the bottom chord of the trusses. New stringers were installed in the approach spans, and the concrete substructure was extended inkind to accommodate the widening. Floor beams were spliced. The original portal brace was replaced in 1930, and again in 1991 with a channel section welded to the inclined end posts. Many of the original riveted connections have been replaced by welds. The truss span was fixed in place in 1970 with new rocker bearings. Most of the operating machinery has been removed.

Historical and Technological Significance: The significance of the 1912 center-bearing swing span bridge fabricated by the Owego Bridge Company of Owego, New York has been lost due to major alterations that have irreversibly changed its appearance and function. Originally measuring 21' out-to-out, and built with no sidewalks, the span was widened approximately 5' in 1930. In addition to splicing many of the transverse members, the diagonals and verticals were strengthened by the addition of section and/or plate welded to the original fabric and replacement of riveted connections with welded ones. In 1970 new bearings for the moveable span were installed, and the bridge was fixed in the closed position. Most operating machinery has also been removed.

The original bridge was built by the Owego Bridge Company of Owego, New York. The company was founded in 1891, and it was a viable concern well into this century. The 1912 span was the first to cross the Rahway River at Lawrence Street, but the present structure resembles the original in profile only. It is too altered to be evaluated as a significant example of a moveable bridge technology that is well represented in New Jersey.

SETTING / CONTEXT The bridge is located in an area of urban transition from commercial to residential structures. The majority of nearby buildings are from the early 20th century. An electrical substation is located adjacent to the bridge. The bridge carries a two-lane street with two sidewalks over the Rahway River.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span encased stringer bridge sits on earlier ashlar piers and abutments with concrete seats. The fascia encasement is paneled and the concrete balustrade with paneled posts is typical of county-designed bridges. Metal fences line the approaches of the bridge. The structure is a representative example of a common bridge type. It is not technologically or historically distinguished.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span thru-girder with rolled floorbeams bridge is supported on scored concrete abutments and a pier that were refaced in 1938. The deck is supported by concrete jack arches set between the stringers. The cantilevered sidewalk has its original iron lattice railing. The bridge is a complete example of a common bridge type, but is not technologically or historically distinguished. An earlier, notable, functioning examples remain in the county (2016059), and there are several in Cranford.

SETTING / CONTEXT The bridge is located in a greenway that follows the Rahway River through Union County. The greenway is surrounded by late-19th century housing in this area. The bridge carries a two-lane street with two sidewalks. The greenway is a narrow park that does not appear to have any distinguishing features that would make it a potential historic district. It is casually landscaped. The bridge predates the greenway, and there is no access to the bridge from within the greenway.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Not Individually Eligible. Potential Rahway River Park, May contribute. Potential Union County Park System Multiple Property nomination, May contribute.
CONSULT DOCUMENTS DOE 10/28/83. SHPO Letter 6/30/95.

SUMMARY The 30'brick arch bridge has ashlar spandrel walls and gauged ringstones at both faces and ashlar footings. Much of the intrados has been coated with gunite. The concrete parapets were added one at a time in 1953 and 1954, detracting from the historic character of the bridge, but its structural integrity is intact. The structure is a short, altered example of a well-represented type from the later-19th century. Other brick arch bridges (2013010) have been evaluated as more noteworthy than this.

INFOR MATION

Bibliography:
Robinson, E. Atlas of Union County, New Jersey. 1882.
Sanborn Insurance Atlas, Rahway, New Jersey. 1923.
1902 Bauer Atlas of Union County.

Physical Description: The one-span brick arch bridge sits on ashlar footings, and has rusticated ashlar spandrell walls and gauged ringstones. The span length is 30', a normal distance for a brick arch bridge. The intrados of the arch has been partially coated with gunite. In 1953 and 1954, concrete parapets were built above the spandrel walls (one each year).

Historical and Technological Significance: The single-arch bridge is the smallest of the four brick arch bridges identified in Union County. The others are all three-span bridges, and all are as well-preserved as this structure, if not better. Though the structural components of the bridge have been preserved, the addition of 1950s style parapets detracts from the historical integrity of the structure.

Through research of 19th and 20th century maps and atlases, it appears that the span has always been the width that it is now. The masonry arch bridges of the 1800s that do remain have in common the width of structure capable of handling the increased road use of the 20th century. This structure, though it is one of the older spans in the county, is not historically distinguished due to the existence of larger and more well-preserved examples of the same type of bridge. Technologically it employs a commonly used design for the situation in which it exists.

SETTING / CONTEXT The bridge is located in a post-World War II commercial area that runs along a busy four-lane county route. The bridge carries 6 electrified tracks of Amtrak's Northeast Corridor over that road. The RR line was developed by several different rail companies, and consolidated by the Pennsylvania Railroad in 1871 to form one main corridor for passenger traffic from New York to Washington. Amtrak took control of the Northeast Corridor in 1971, after the Penn Central RR went bankrupt.

SETTING / CONTEXT The bridge is located in downtown Westfield, in an area of 1960s commercial development. It carries a two-lane street with sidewalks over a stream that is part of the municipal storm water collection system.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY According to the County Engineer, the hidden underground single-span stringer bridge sits on concrete abutments. In 1936 most of the original superstructure was replaced with encased stringers. The structure mostly remains a stringer bridge, although in 1985 part of it was replaced with a slab. The bridge is not technologically or historically distinguished.

SETTING / CONTEXT The bridge carries a two-lane road with one sidewalk over one abandoned track. The tracks run through an early-20th century industrial area. The Central RR of NJ developed the line in the 1830s as a streetcar line, and it soon evolved into a larger system, stretching from Elizabeth to Somerville. It was four-tracked by 1882. The early-20th century was marked by grade-crossing elimination projects, resulting in several bridges in this area.

SETTING / CONTEXT The bridge is located adjacent to 1920s Colonial Revival apartment complex. The bridge carries a two-lane road with two sidewalks over three electrified tracks of New Jersey Transit's Morristown Line. The Morristown Line was built as the Morris and Essex RR in 1835, and was later leased to the Delaware, Lackawanna and Western RR. The DL & W developed the line into a passenger route, building a more efficient route, the Boonton Line, for freight. NJ Transit now operates the tracks.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed steel frame bridge appears to be a stringer span on concrete abutments with wingwalls. The rivet-connected steel frames are visible only under the deck, where the exposed beams are haunched as they enter the concrete abutments that encase the rolled steel columns. The structure is significant as an example of an uncommon bridge type. Only one other steel frame bridge has been identified in the state, also from 1937 (0917150). It's unknown if the DL&W RR built any others of this type.

INFOR MATION

Bibliography:
Condit, Carl. American Building Art 20th Century. 1961.
Mensch, L.J. "Early Use of Rigid Frame Bridges." Civil Engineering. Vol. 5, No. 10 (October, 1935).

Physical Description: The skewed one-span steel frame bridge has the appearance of being a stringer bridge on concrete abutments. The rolled beam section of the frame is exposed steel. The seven beams are haunched as they enter the concrete abutments that are really the encasement for the rolled section columns of the steel frame. The haunched connections are built up of plates and angles that are rivet-connected to the rolled sections. The knee, which have the great concentration of stress distributions, has riveted stiffeners.

The concrete abutments are flanked by wingwalls at all four corners of the bridge. A high paneled concrete parapet crosses the bridge at both faces and continues above each wingwall for 5'-10'. Pedestrian fencing has been added to the top of the parapet along the sidewalks. The approach guide rails are fixed to the parapets.

Historical and Technological Significance: The steel frame bridge is technologically distinguished as a complete example of a pre-World War II bridge type that is not common in the state of New Jersey. The structure, built in 1937, is the only identified, highway-related example of its type in Union County, and is one of only two documented pre-World War II examples in the state.

The Delaware Lackawanna and Western Railroad built the bridge in 1937, long after their main grade crossing elimination campaign in the City of Summit. They built at least seven girder bridges in Summit in 1905, as they strove to improve their commuter service to New York City. It is not known if other steel frame bridges were built by the DL&W RR. The right-of-way, now used by NJT as its Morristown line, was originally used for both freight and passenger service. When traffic became heavy and profits were suffering, the D L & W built the Boonton cutoff to more efficiently handle freight. This portion of the line remained the commuter line, and is still used mainly for that purpose.

The other steel frame structure identified (0917150) was also built in 1937. It is located on the historically and technologically significant limited-access New Jersey approach to the Lincoln Tunnel. The tunnel and approach were designed for by the Port Authority of New York, Othmar Ammann, Chief Engineer.

Not to be confused with the reinforced concrete rigid frame bridge that was first used in this country in the early 1920s on Westchester County, New York parkways, the steel rigid frame bridge was largely the product of the invention of electric arch welding. Welding permitted the transformation of the individual elements, like posts and beams, into a continuous unit in which the size and shape of each member can be calculated exactly and entirely on the basis of the role it plays in the total action of the frame. As a consequence, the quantity of material in the member for a given load can usually be reduced. A welded joint could theoretically be made as strong as the original solid metal if complete fusion was obtained. This was viewed as an advantage over riveted connections. Rigid steel frames were used in buildings beginning in 1920 at the factory of the Electric Welding Company of America at Brooklyn. The concept of a rigid frame bridge was developed in reinforced concrete in Europe around the turn of the century, but rigid frame bridges were not built in this country until the early 1920s. Examples of steel rigid frame bridges are rare in New Jersey.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. It is not part of a grade crossing elimination campaign or other major improvement campaign. The significant boundary is limited to the structure itself.

CONSTRUCTION DT 1920 **ALTERATION DT** 1987 **SOURCE** COUNTY RECORDS

DESIGNER/PATENT H. W. VETTER, COUNTY ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a two-lane road over a minor stream on the southern edge of the residential area in Belvidere. Altered late-19th century dwellings are adjacent to the north side of the bridge. The area to the south is agricultural.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The stringer bridge sits on rubble stone abutments with a concrete toe wall at the northwest corner. The stringers support a glued laminated deck with railings that were placed in 1987. Pipe railings are set in the wingwalls at three corners of the bridge. The structure has been significantly altered, and is not a technologically or historically distinguished bridge because it is a common type.

SETTING / CONTEXT The bridge is located in a potential historic district in the town of Bloomsbury. It carries a main street over the Musconetcong River, the boundary between Warren and Hunterdon Counties. The bridge has two lanes for traffic and two sidewalks. Both sides of the river have 19th century residences and commercial structures that contribute to the district, as does the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible. North Bloomsbury Historic District, Eligible. Contributing.
CONSULT DOCUMENTS SHPO Opinion 3/3/93 12/09/99.

SUMMARY The pin-connected Pratt thru-truss bridge sits on stone abutments, the southern one with a concrete toe wall. The verticals and top chords are built-up members, while the diagonals and the bottom chords are eyebars. 1936 alterations include weld-connected bars strengthening some of the members. In 1994 the bridge was widened. It is one of four thru truss bridges in the county. The bridge is individually eligible for listing in the National Register of Historic Places under Criterion C. In addition, the bridge is eligible under Criteria A and C as a contributing element of the North Bloomsbury Historic District

INFOR MATION

Bibliography:
Darnell, Victor. Directory of American Bridge Building Companies, 1840-1900. Washington, DC: 1984.
Industrial Directory of New Jersey. 1906-1930.
Sanborn Insurance Maps; Bloomsbury. 1909-1923.
Wacker, Peter. The Musconetcong Valley of New Jersey. 1968.

Physical Description: The skewed 6-panel pin-connected Pratt thru truss bridge is supported on an ashlar substructure. Although it was strengthened in 1936 with additional members welded to the original trusses, the span retains much of its original fabric and configuration, including cantilevered sidewalks with metal lattice-pattern railings. The inclined end posts and top chord are built-up members of channel with cover plate and laced stiffening. The verticals are toe-out channels with lacing on each face, and the diagonals and bottom chord are eye bars, some of which have stamped eyes and some of which have looped forged eyes. Each braced portal brace with lattice infill is topped by a bridge plaque. The floor beams are rolled. A low lattice railing separates the roadway from the sidewalks. Strengthening is limited to the outside panels, which have additional vertical hangers, diagonals, and a sub diagonals. Such modifications to pin-connected thru truss bridges from the late-19th century are not uncommon.

Historical and Technological Significance: The pin-connected Pratt thru truss bridge was built in 1892, and it is significant on its own merits as oldest and one of the most complete "high" truss bridges in the county (Criterion C). Although the span has been modified, as early as 1936 when it was strengthened by the addition of welded members, most of the original fabric, including railings at both the sidewalks and the truss lines, remains in place, and the span still functions as a pin-connected bridge.

The bridge is also a contributing resource in the North Bloomsbury Historic District. The district is comprised of a late eighteenth/early nineteenth century crossroads village that developed along the New Brunswick turnpike in Hunterdon County. The district includes 14 residences with their associated outbuildings, one small industrial complex, and a bridges, as well as farm fields, pastureland, wood lots, and bottomland of the Musconetcong River. Although this area traditionally supported an agricultural way of life [which continues to the present], historically, a mid-eighteenth century forge was located in the immediate area and the river supported gristmills, distilleries and an early iron industry.

The North Bloomsbury Historic District is significant because it represents a small crossroads community that was developed by and is associated with the locally prominent Smith family, who were successful members of the local agricultural community. It is also significant for its well preserved examples of stylish Georgian and Federal period architecture, which represent some of Warren County's finest early nineteenth century architecture. The period of significance for the district is 1780 to 1900.

Four pin-connected thru truss bridges survive in Warren County (2102307, 2102015, 2160153, 2100718). Three were built by the county, and one was erected by the Lehigh Valley Railroad to carry a local road over its right-of-way. Because of the scarcity of the once-common bridge type in Warren County, all four of the thru trusses bridges were evaluated as significant because they are rare local examples of a structure type that played an important role in the historical development of the county.

The Toledo Bridge Company of Toledo, Ohio fabricated the Church Street bridge. Robert W. Smith of Tippicanoe City, Ohio founded the company in 1867, and in 1869 moved it to Toledo under the name of the Smith Bridge Company specializing in Smith's patented wood and iron bridges. In 1890 Smith sold the company and the new owners changed the name to the Toledo Bridge Company. In 1894 the company had an annual capacity of 6 thousand tons, a respectable but not large figure for the time. In 1901, the company was purchased by the American Bridge Company as part of its multi-company merger.

Boundary Description and Justification: The bridge is individually eligible and it is located within a historic district. The district is bounded by the Musconetcong River on the south, and by an historic tree line along agricultural fields to the north. Eastern and western boundaries are somewhat irregular in order to include specific properties.

DESIGNER/PATENT H. W. VETTER, COUNTY ENGINEER **BUILDER** DOVER BOILER WORKS

SETTING / CONTEXT The bridge is located in an area of late-20th century commercial development. The bridge carries a two-lane county route over the Musconetcong River, which is the boundary between Warren and Morris Counties. The joint-county bridge was designed by the Warren County Engineer H.W. Vetter, and sent for approval to W. Hopkins, Morris County Engineer. Dover Boiler Works built bridges throughout the northern part of the state, this being a late example of their work.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span stringer bridge is supported by stone abutments and a concrete cutwater pier. Concrete wingwalls flank the abutments and form approach parapets. The stringers are completely encased and they support a concrete deck. The railings are composed of concrete posts with pipe metal rails. The bridge is scheduled for replacement in 1993. It is a representative example of a common bridge type built by a prolific local contractor, and is not technologically or historically distinguished.

DESIGNER/PATENT H. W. VETTER, COUNTY ENGINEER **BUILDER** BALL (CONTRACTOR)

SETTING / CONTEXT The bridge is located in an area of active farms and woods. The one-lane structure carries a two-lane country road over the stream. Two approach spans cross a tributary and the floodplain of the stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span stringer bridge is supported by a rubble stone substructure. The pier has been altered with the addition of a concrete cap at the ends of the pier. The bridge was widened in 1988 with the addition of stringers. Two short spans form the approaches to the bridge over the floodplain of the Paulins Kill. They are the same width as the bridge, with a beam guiderail continuous over all the structures. The bridge is not technologically or historically distinguished.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 3-span, 32'-long stone arch bridge of rubble-coursed fieldstone has small, low-rise arches. The stone parapets are topped with replacement concrete capstones. Ca. 1972 the bridge was repointed. This is one of 9 stone arch and 6 multi span stone arch bridges in the county. It is individually eligible for listing in the National Register of Historic Places under Criterion C as a representative example of stone multi arch technology. The essential character defining features remain: the arches, the voussoirs, the rubble-coursed fieldstone spandrel walls and parapets. It is located in a sparsely developed wooded area and therefore maintains integrity of setting and feeling.

 # SPANS 2 **LENGTH** 53 ft **WIDTH** 17.9 ft

CONSTRUCTION DT 1914 **ALTERATION DT** **SOURCE** PLANS/COUNTY RECORDS

DESIGNER/PATENT F. W. SALMON, COUNTY ENGINEER **BUILDER** ABER (CONTRACTOR)

SETTING / CONTEXT The bridge is located in a wooded and agricultural area. It carries a two-lane road over a minor river. 25 yards south of the bridge is a culvert built in 1933 which spans a tributary of the river. The structures are related only by location, not by appearance or physical ties.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span stringer bridge is supported on concrete abutments and a pier. The substructure has toe walls added for scour protection around the base of all components. The stringers are spanned by concrete jack arches, with deteriorating corrugated metal liners. The bridge railings have concrete posts and metal pipe rails. Gabion wingwalls are located along the south bank. The bridge is the only unaltered example of a common county bridge type built 1911 to 1914, of which at least 7 remain.

INFOR MATION

Bibliography:
Warren County Engineer. Bridge Files.

Physical Description: The two-span stringer bridge sits on concrete abutments and a pier, all of which have toe walls. The original steel stringers are spanned by concrete jack arches that have portions of the deteriorating corrugated metal liners remaining in place. Metal pipe rails are supported by pipe posts as well as concrete posts. The bridge is located in an undeveloped area, and carries a winding road over a minor river that crosses Warren County, out letting into the Delaware River at Belvidere.

Historical and Technological Significance: The Cemetery Road bridge is significant as a well-preserved example of a steel stringer and concrete jack arch bridge, a type that is becoming increasingly rare in the county and state (Criterion C). Steel stringers were a common bridge type at the turn of the 20th century and were frequently combined with brick jack arches as a means of supporting flooring systems. In the first decade of the 20th century, concrete jack arches replaced brick jack arches as a transitional step in the movement toward concrete slab decks, which eventually became popular because of their economy and strength. In Warren County, County Engineer F. W. Salmon designed numerous stringer and concrete jack arch bridges in the years leading up to WWI. At least seven bridges from 1911 to 1914 are known to survive (2101306, 2102251, 2102237, 2102204, 2100530, 2101356, 2101202), but the Cemetery Road bridge is the only one that has not been altered by the addition of stringers to one or both faces, or by changes in railing treatment. The subdivided pipe and concrete post railings are a distinctive detail of Warren County bridges from this period.

Boundary Description and Justification: Because it is the span itself that is evaluated as significant, the boundary is limited to the superstructure and substructure of the bridge itself. While the surrounding rural and undeveloped acreage provides an appropriate setting for the bridge, it does not contribute to its significance.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1913 stringer bridge with concrete jack arches is supported on rubble stone abutments. In 1983 the bridge was widened with the addition of steel stringers on concrete abutment extensions. The railings are composed of concrete posts with metal pipe rails. The bridge is 1 of at least 7 surviving early 1910s steel stringer bridges with concrete jack arches in the county. The altered example is not historically or technologically distinguished and better preserved examples survive (2101202).

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Listed. Listed. Warrington Stone Bridge. 12/16/1977.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The six-span stone arch bridge is reportedly the largest stone arch roadway bridge in New Jersey. The overall length of the bridge is 183'-3", and it is 16' wide. The spans vary from about 17' to over 23'in length. It is a significant example of masonry arch technology because of its length, number of spans, and condition. The bridge was built by unidentified local craftsmen according to the National Register nomination.

CONSTRUCTION DT 1896 **ALTERATION DT** 1925, 1935, 1990 **SOURCE** PLAQUE/COUNTY RECRDS

DESIGNER/PATENT UNKNOWN **BUILDER** HAVANA BRIDGE WORKS, NY

SETTING / CONTEXT The bridge is located in a wooded, sparsely developed area, near the junction of a state route and a local road. The bridge carries the one-lane local road over a river. Another pony truss bridge is located 100' to the south. The Havana Bridge Works was in business from 1896 and was an outgrowth of W. H. Shepard's Sons Bridge Company and the predecessor of Rochester Bridge and Construction Company. Havana Bridge Works was located in Montour Falls, New York, which was once Havana, NY.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-preserved pin-connected Pratt pony truss sits on one field stone abutment and one concrete abutment. The slightly skewed bridge is composed of built-up rolled section members, batten plates and lacing bars. Eyebars form the bottom chords and the diagonals. The plaque of Havana Bridge Works and uncommon open-face finials are fixed to the top chord. The span ranks as one of the oldest and most complete pony trusses in the county. It is also significant due to its documented fabricator.

INFOR MATION

Bibliography:
Darnell, Victor. Directory of American Bridge-Building Companies 1840-1900. 1984.

Physical Description: The 6-panel pin-connected Pratt pony truss bridge stands in a remarkable state of preservation, complete with its mid-top chord bridge plaques. The top chord and inclined end posts are composed of toe-out angles with top cover plated and batten stiffeners. The verticals are angle section set back-to-back with a lattice web. The diagonals, counters, and bottom chords are eye bars. The verticals are attached to the upper chord by an L-shaped strap through which the pin passes. The detail is not unusual or a patented feature. The most distinctive detail is the open-face ball finial set at each of the top chord corners. They have not been identified on any other metal truss bridge in the state. The floor beams are rolled I section and are fitted with lateral bracing. Any original railings have been replaced by modern but compatible wood railings.

Alterations to the bridge include in 1925 replacing the original west ashlar abutment with a concrete abutment and raising the west end of the truss by 18 inches; in 1935 strengthening and repairing the bridge with welded members including subdiagonals attached at the lower panel points by welded plates, outriggers, and repairs to the lower portions of the inclined end posts; and, in 1990 installing a glue-laminated wood deck. The alterations do not compromise the truss's integrity of design.

Historical and Technological Significance: The Pratt pin-connected pony truss bridge erected in 1896 by the Havana Bridge Works is a locally significant example of its type (Criterion C). It ranks as the best preserved metal truss bridge in the county, and in addition to representing the important structure type, the span chronicles the history of a small regional bridge fabricating firm whose history is not unlike other 19th-century fabricators who saw prosperity in manufacturing metal bridges and who distributed their products through a network of agents who worked with county freeholders. The Havana Bridge Company was established as W.H. Shepard's Sons Bridge Company in Havana, later Montour Falls, New York in 1891. It was reorganized and restyled the Havana Bridge Works in 1896, according to Victor Darnell, and it was the predecessor to the Rochester Bridge and Construction Company. The 1898 bridge plaque identifies Havana Bridge Works as being located in Elmira, New York, not in Montour Falls.

Boundary Description and Justification: Because the bridge is individually significant, it is the span alone (substructure including wingwalls and superstructure) that is evaluated as significant.

TOWNSHIP OXFORD TOWNSHIP

TYPE STRINGER **DESIGN** **MATERIAL** Steel

 # SPANS 1 **LENGTH** 30 ft **WIDTH** 28 ft

CONSTRUCTION DT 1910ca **ALTERATION DT** Demolished **SOURCE** STYLE/COUNTY RECORDS

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located in the Oxford Industrial Historic District on a 19th century residential street with altered houses. The Oxford Furnace is one block to the north of the bridge. The span carries a two-lane street with sidewalks over a creek that runs through the historic town. The period of significance of the district is 1741-1930. County records indicate that the bridge was built prior to 1914.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Not Individually Eligible. Listed. Oxford Industrial Historic District 08/27/1992. Contributed.

CONSULT DOCUMENTS SHPO Letter 06/30/95 03/12/01.

SUMMARY The one-span stringer bridge bears on ashlar abutments. The stringers are exposed steel, with the top flanges embedded in the concrete deck. The railings on the bridge faces and at the curb are well-preserved original metal lattice work with finials on the end posts. The bridge is significant due to its location within the historic district in Oxford, and it contributes to its character. By itself, the bridge is not technologically distinguished.

INFOR MATION

Bibliography:
Oxford Historic District Nomination. 1976.
Warren County Engineer. Bridge Files.

Physical Description: The single-span steel stringer rests on ashlar abutments. The top flanges of the stringers are imbedded in the concrete deck. The railings on the bridge faces and at the sidewalk curb are well-preserved original metal lattice work with finials on cast iron end posts.

Historical and Technological Significance: The c.1910 steel stringer bridge is within the boundaries of the Oxford Industrial Historic District and fits within the historic themes of the district's areas of significance that include industry, community development, and transportation (Criterion A and C). The bridge is not individually eligible but is a contributing resource within the district's period of significance (1741-1930). Oxford began in 1741 as an iron furnace and grew into a technologically and historically significant factory town in the mid-19th century in part as a result of the construction of the Warren Railroad. In the late-19th century the town declined as the iron industry moved further west, and operations ceased in the 1920s. The district is significant because its architecture and landscape reflect the rise and decline of a regionally important industry. The bridge carries the town's historic primary north-south thorofare over Furnace Brook, and until the arrival of the railroad this route carried the products of the iron furnace to market.

County records indicate the present Washington Avenue bridge was in place in 1914. No original plans were located, but the railings and concrete deck, which appear to be original, stylistically date the bridge to c.1910. Furnace Brook passes through the center of town and the bridge is one of two crossings (the other is 2111154, NJ 31/Mill Street over Furnace Brook) that allowed for development on both sides of the stream. The surrounding structures are 19th-century residences. The simply-supported steel stringer bridge was a common early-20th century bridge type that was used widely in Warren County.

Boundary Description and Justification: The bridge is within the boundaries of the Oxford Industrial Historic District as delineated in the USGS Quad Maps accompanying the National Register nomination. The bridge was not rated in the original historic district nomination. The boundaries of the district include both sides of the stream surrounding the bridge.

DESIGNER/PATENT CORNELIUS C. VERMEULE,CONS.ENG **BUILDER** F. H. CLEMENT & COMPANY

SETTING / CONTEXT The bridge is located adjacent to a T intersection. The bridge carries a busy two-lane road over a stream that was the r-o-w of the Morris Canal. The construction of the bridge in 1927 was funded by the Morris Canal and Banking Company, as part of the canal abandonment program. The area once used water from the creek to power industrial buildings.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Morris Canal. 10/01/1974. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed one-span encased stringer bridge sits on concrete abutments with wingwalls. County forces added a sidewalk on the upstream face in 1934. The bridge was widened again in 1968 by the addition of prestressed box beams and widened abutments. A new railing encloses the bridge on the widened face, opposite a paneled concrete parapet on the original face. The altered bridge is an example of two common bridge types, and is not technologically or historically distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries one lane of a quiet country road over a minor stream that is the boundary of the town of Phillipsburg. One end of the bridge also appears to be adjacent to the NR-listed Morris Canal R-O-W. The area surrounding the bridge does not appear to have historic district potential because of several modern, intrusive dwellings, but architecturally significant 18th- and 19th-century houses are within sight of the span.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The half-hip Pratt pony truss bridge sits on an ashlar substructure with concrete toe walls at the south abutment. The span has been significantly altered. In 1937 welded plates and bars were added to nearly every member. These modifications and the loss of original railings alter how the bridge functions and severely compromise its technologically or historically significance. It is an altered example of a common bridge type. The ca.1900 date is based on construction details.

SETTING / CONTEXT The bridge is located in a wooded area with scattered residences. The one-lane bridge carries a winding road over a stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The one-span welded pony truss bridge is set on stone abutments, one of them with a later concrete buttress. The truss is composed of rolled I-sections welded together with gusset plates. The floorbeams are built-up with flange angles riveted to the web plates. Rolled stringers support a timber deck. The bridge replaces a pin-connected Pratt pony truss. It is one of three welded pony trusses crossing the same creek in Pohatcong Township. Although the bridge conveys the concept of the truss design, it no longer retains integrity of materials or design and is not individually eligible for listing in the National Register of Historic Places, nor does it currently contribute to an identified historic district.

SETTING / CONTEXT The bridge is located in a well-preserved mill complex dating to the early-19th century and including a mill with its machinery and the miller's dwelling. The bridge contributes to the historic character of the National Register-listed complex. The one-lane bridge carries a narrow road over a stream.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Hixson/Skinner Mill Complex. 12/02/1982. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span pony truss is set on concrete abutments with stone wingwalls along the south abutment. The truss is built-up of channel sections, lacing, batten and cover plates and eyebars, with some additional welded bars to the diagonals and bottom chord from 1936. At the ends of the top chord, decorative plates cover the end of the rectangular section. Despite the alterations, the bridge is sited well enough between the mill and the miller's house to be a contributing element to the district.

CONSTRUCTION DT 1936 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT **BUILDER** WELDING ENGNRS INC. PHILA

SETTING / CONTEXT The bridge is located in an area of scattered residential structures from the 19th century. The two-lane bridge carries a winding road over a stream near the intersection of two roads. The bridge was constructed by Welding Engineers Inc., of Philadelphia, who built three similar bridges over this creek. This is the earliest and largest of the three bridges. It replaced a 1882 pin-connected pony truss bridge that was built by Dean and Westbrook.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Potential rural historic district, May contribute.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The welded Warren pony truss bridge sits on stone abutments. The south abutment has concrete toe walls and wingwalls. Most of the members are rolled I-sections, but the bottom chord is built of two toe-out angles with batten plates and the end verticals are channels. The floorbeams and stringers are rolled sections as are the outriggers and railings. The bridge is one of at least 10 pre-1946 welded truss bridges in the state, and one of 3 over the same creek. The bridge is not technologically distinguished and is therefore not individually eligible for listing in the National Register of Historic Places. The bridge may be a contributing element of an historic district.

SETTING / CONTEXT The bridge is located in a rural area, adjacent to working farms. The one-lane bridge carries a winding local road over a creek. The Belvidere-Delaware RR has a bridge crossing the creek just downstream.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The pin-connected Pratt thru-truss bridge is supported on ashlar abutments with stone wingwalls. The south abutment has a toe wall. The members are composed of toe-out channels with lacing and cover plates, and eyebars, a few with welded bars from 1936. A sub-diagonal was welded in the end panels, built of channel sections and batten plates, and welded railings were added. The bridge is a significant, well-preserved example of its type. It is one of 4 noteworthy thru truss spans in the county.

INFOR MATION

Bibliography:
Warren County Engineer: Bridge File.

Physical Description: The 118'-long 6-panel half-hip Pratt thru truss bridge with pinned field connections is supported on ashlar abutments with concrete toe walls. While the end panels have been strengthened with welded additional members (hangers, diagonals, chords, and subdiagonals) and corner bracing has been welded to the upper lateral braces at the verticals, the trusses are otherwise relatively complete. The inclined end posts and top chord are built up box members composed of channels and cover plate while the verticals are toe-out laced channels. The diagonals and counters are bar stock with both looped and stamped eyes. The bridge exhibits no unusual or patented construction details, but it is a complete example of a traditionally composed pin-connected span with integrity of setting.

Historical and Technological Significance: The pin-connected Pratt half hip thru truss bridge is a late and altered example of its design, but it is one of only two (2100718 is the other example) that remain in the county, and it is thus significant as a rare survivor of a once-common type (Criterion C). County records indicate that it was erected in 1901, but the fabricator is not known. Alterations are limited primarily to the end panels where additional members were welded to the original hangers and diagonals to strengthen the span. A subdiagonal was also added. This work was done in 1936.

A total of four (2 Pratts, 2 double-intersection Warrens), thru truss bridges survive in Warren County (2102307, 2102015, 2160153, 2100718). Three were built by the county, and one was erected by the Lehigh Valley Railroad to carry a local road over its right-of-way. Because of the scarcity of these once common bridge types in Warren County, all four of the thru truss bridges were evaluated as significant because they are rare local examples of a structure type that played an important role in the historical development of the county. The Pratt truss became the most popular of the many truss designs that were experimented with in the 1870s. It was favored because of its overall simplicity, economy of material, ease of fabrication, and strength. The Pratt truss played a significant role in the general acceptance of metal truss bridges for highway use in the last quarter of the 19th century, and by 1900, it was the most common pin-connected bridge type in the nation in both the high and low truss designs.

Boundary Description and Justification: Because it is the span itself that is evaluated as significant, the boundary is limited to the superstructure and substructure of the bridge itself. While the surrounding rural and undeveloped acreage provides an appropriate setting for the bridge, it does not contribute to its significance.

 # SPANS 3 **LENGTH** 41 ft **WIDTH** 91.6 ft

CONSTRUCTION DT 1938 **ALTERATION DT** 1954 **SOURCE** PLANS

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge is located in an agricultural farming area with some late-20th century commercial structures along the highway. It carries a busy four-lane divided highway with a grassy median over a creek. The bridge is noticeable along the highway only by the structure identification marker.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete rigid frame bridge is continuous over the three spans. The 1938 structure was widened in 1954 with a similar three-span continuous frame which extended the width by 55'. The altered bridge is not technologically innovative nor is it historically distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** S. H. SHIELDS

SETTING / CONTEXT The bridge is located in an area of modern residential subdivision development with a few 19th century dwellings interspersed. It carries a two-lane road over a minor stream.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span stringer bridge sits on a rubble-coursed stone abutment and a concrete abutment, both of which have stone wingwalls. The stringers are spanned by concrete jack arches. Vertical tie rods from the crown of the arches connect to channel sections welded to the bottom flanges of the stringers for added lateral stability. The bridge was widened in 1932, and the new stringers do not have jack arches. The altered bridge is not technologically or historically distinguished.

SETTING / CONTEXT The bridge is located in a wooded setting on the northwest edge of the village of New Hampton. It is adjacent to poorly maintained 19th century buildings. Ruins of a mill are on the property adjacent to the bridge. The bridge carries one lane of a rural road over the Musconetcong River, the boundary between Warren and Hunterdon Counties.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Listed. Listed. New Hampton Pony Pratt Truss Bridge. 07/26/1977.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The cast and wrought iron Pratt pony truss bridge is one of the most technologically significant spans in the state. The 8-panel truss represents the transition from wood to metal truss spans, and it is the design of noted engineer F. Lowthorp and foundryman W. Cowin of Lambertville. It is the earliest of 3 similar spans in the area. In 1991 the north end post suffered severe impact damage, but it was sensitively repaired, preserving the integrity of the structure. The bridge is well-preserved.

CONSTRUCTION DT 1913 **ALTERATION DT** **SOURCE** PLAQUE/COUNTY RECRDS

DESIGNER/PATENT F. W. SALMON, COUNTY ENGINEER **BUILDER** M.IRVING DEMAREST, CONTR.

SETTING / CONTEXT The bridge is located in a wooded area, near the intersection of Sarepta Road with busy US 46. The bridge carries the two-lane local road over a stream.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-proportioned reinforced concrete deck arch bridge is bounded by concrete wingwalls on the south bank and rubble-course stone wingwalls on the north side. The railings are concrete posts with metal pipe rails. Over the wingwalls are panelled concrete parapets. The roadway rises in a crest curve over the arch bridge. The span ranks among the earliest and most handsome of the 15 deck arch bridges in the county and is a well-preserved, representative example of the important bridge type.

INFOR MATION

Bibliography:
Musti, M. Warren County New Jersey 1931. 1931.
Warren County Engineer. Bridge Files.

Physical Description: The well-proportioned 43'-long reinforced concrete elliptical deck arch bridge has plain spandrel walls. The roadway rises in a crest curve over the arch, and the clear span is marked by a metal and concrete railing composed of plain concrete posts and pipe rails. The bottom level of the pipe railing is subdivided. The approaches are marked by paneled parapets. Those at the T-intersection are curved which adds to the graceful appearance of the well-preserved bridge.

Historical and Technological Significance: The well proportioned and well preserved elliptical-shape deck arch bridge built in 1913 ranks as the most distinguished example of the bridge type that was commonly used by the county engineer in the 1910s (Criterion C). Designed by county engineer F. W. Salmon, the Sarepta Road arch, the earliest non-railroad related reinforced concrete deck arch bridge remaining in the county, reflects the trend of early-20th century county engineers to increasingly turn to reinforced concrete as the strong and economical replacement of earlier stone and metal truss bridges that were proving too light for 20th-century load requirements. The Sarepta Road bridge, one of eight built in the 1910s that remain in service today, is also locally significant in that it embodies details that are typical of 1910s and 1920s Warren County bridge. The railing, with concrete posts and nicely detailed pipe rails, is a type frequently seen on county-designed bridges as is the paneled concrete parapet used to mark the approaches. It is a fine summation of the county principle of "an achievement in design that has been the beauty of structure without sacrifice of strength or increase of cost" (Musti, p. 38).

Boundary Description and Justification: Because it is the technical and historical importance of the bridge that is significant, the boundary is limited to the structure itself. This includes the sub and superstructure as well as the wingwalls and approach parapets.

SETTING / CONTEXT The bridge is located in a ca.1900 residential area that does not have historic district potential. The structure carries a two-lane county route over a river.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The center three arches of the nine-span bridge have metal plate lining while the other six have been coated with gunite. The bridge was widened on the west face in 1934 with metal plate and reinforced concrete arch additions. The western spandrel wall was reconstructed of stone, but laid randomly, not carefully coursed as the original eastern spandrel walls are. The bridge is an extensively altered example of stone arch technology.

INFOR MATION

Bibliography:
Leferts, H. Leedom, Jr., and David R. Piefer. Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. 1979.
Mustin, M. Warren County, New Jersey, 1931. Camden, NJ: 1931.

Physical Description: The 9-span stone arch bridge is set in a residential area and has been widened to accommodate modern traffic concerns. The intrados of the widened portions of the structure are lined with metal plates at the 3 central spans, and are constructed of concrete at the 3 spans on each end. The original arches have been coated with gunite on the intrados. The eastern spandrel wall is neatly constructed of coursed rubble, but the western spandrel was randomly rebuilt. The ringstones are neatly gauged at both faces of the structure. The parapets with replacement concrete coping stones are low in comparison with the leveled roadway, approximately one foot high at the ends of the structure.

Historical and Technological Significance: The South Bridgeville Road bridge (1836) has been significantly altered and no longer retains its original design. In 1934 the bridge was widened with concrete and metal arch additions to meet modern traffic concerns. The west stone spandrel wall and parapets with concrete coping were rebuilt in a method not conforming to modern preservation standards. Although the bridge is the oldest and longest-span stone arch surviving in the county, better preserved examples exist to illustrate the type of stone arch bridge technology that was used in the county throughout the 19th century. The Historic Bridge Survey evaluated at least nine surviving stone arch bridges in Warren County including the historically and technologically significant Brugler Road over Paulins Kill (2101311, c.1860, Knowlton Township) and Stephensburg Road over Musconetcong River (2101607, 1860, Mansfield Township). The latter is rated a contributing structure to the National Register listed Miller Farmstead.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The double-intersection Warren thru-truss bridge is supported by gunite-coated abutments with wingwalls. The riveted truss is built of angles and batten plates for diagonals and the bottom chord, with channels and cover plates for the top chord and posts. In 1934, some diagonals were strengthened with welded channels. There are also bolted repairs. Despite the modifications, the span retains much of its original fabric, including handsome railings and is a rare example of an uncommon truss type.

SUMMARY The single span stringer bridge is supported on stone and concrete abutments. The original stringers are encased in concrete and are on stone abutments. The bridge was widened ca.1985 with exposed stringers on concrete abutment extensions. The bridge railing has concrete posts and two metal pipe rails on the original side and a beam guiderail at the other. The bridge is a representative example of a common bridge type. It is not a technologically or historically distinguished structure.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The rivet-connected Warren pony-truss bridge is supported on concrete abutments. Some of the built-up diagonal members have been strengthened with welded cover plates, as have the rolled floorbeams. The bottom chord has been replaced with angle sections and welded batten plates, bolted to the gusset plates at the panel points. A lattice railing is welded to the truss. The bridge is an altered example of a type that is common in the region, and is not technologically distinguished.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span stone arch bridge has been extensively altered. Ca. 1955 the piers were encased in concrete, forming cutwater piers at the upstream face. In 1988 the stone spandrel walls were insensitively repointed, and metal pipe weep holes were installed through the stone parapets at deck level. A concrete cap was added to the top of the parapets. The bridge is one of nine stone arch bridges in the county, but it is not well-preserved.

CONSTRUCTION DT 1907 **ALTERATION DT** **SOURCE** INSCRIPTION/PLANS

DESIGNER/PATENT DL&W RR OFFICE OF ENGINEER **BUILDER**

SETTING / CONTEXT The bridge is located in a residential area dating to the late-19th century. It crosses a two-lane state highway, carrying a two-track right-of-way at the narrowing of the line from several tracks down to one track. The line was developed as the Warren Railroad and was used as the main line of the Delaware Lackawanna & Western in New Jersey prior to the construction of the New Jersey Cutoff.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Delaware, Lackawanna & Western Railroad Old Main Line Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 09/24/96, Letter 03/12/01.

SUMMARY The 1-span deck arch bridge has skewed wingwalls retaining fill that was used to elevate the line through the urban area. It has low curbs at the top of the spandrel walls to prevent ballast from leaving the deck. Built by the DL&W Railroad in 1907, this structure can be seen as a significant precursor of the DL&W New Jersey Cutoff, built 1907 - 1911. The DL&W was important in the adaptation and acceptance of the application of concrete technology to railroad usage. Railroad usage of concrete technology initially lagged behind roadway usage because engineers were uncertain about the material's properties -- specifically how it would react under the enormous stresses that occur where a massive dynamic load (train) crosses a structure. This bridge is individually eligible for listing in the National Register of Historic Places under Criterion C as an early example of the use of concrete arch technology by the railroad industry, and as a contributing element of the Old Main Delaware Lackawanna & Western Historic District under Criteria A and C.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The four-span concrete slab bridge bears on concrete piers and abutments. The pier bents have four columns and arched struts. The slab deck is covered with ballast, and is flanked by concrete parapets that have been detailed to look like the typical State-designed concrete balustrades of the 1930s and early 1940s. The bridge is not technologically or historically distinguished, as it is a type commonly used for railroad overpasses.

DESIGNER/PATENT H. W. VETTER, COUNTY ENGINEER **BUILDER**

SETTING / CONTEXT The bridge is located at the intersection of a state highway and local roads. The large intersection is surrounded by 19th and 20th century commercial structures, and lies within the boundaries of the Oxford Historic District. The period of significance of the State Register district includes the years of 1741-1930, when the iron industry in the area was prospering. There was mining and furnace blasting dominating the town during those years.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Oxford Industrial Historic District 08/27/1992. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single span bridge is a combination of several structures and has been altered such that although within the time period and boundaries of the Oxford Historic District it is not a contributing structure. The 1920 bridge was a steel stringer on concrete abutments built near a short-span stone arch bridge (c.1875) carrying an adjacent street. In 1953 a concrete slab was built between the two bridges to form a larger intersection of the two roads. The bridge is not historically distinguished.

INFOR MATION

Bibliography:
Bridge Files and Plans, No. 2111154. NJDOT. 1920, 1953.
"Oxford Industrial District." National Register Nomination. NJ SHPO. 1992.

Physical Description: The single-span bridge is a composite of stone arch, steel stringer, and reinforced-concrete slab construction. The oldest northern portion of the bridge is an approximately 19'-span stone arch (c.1875) that carries Mill Street into the intersection with NJ 31. The southern end is a skewed 30'-span encased steel stringer (1920) built from approximately 18' to 53' upstream from the stone arch. The middle section of the bridge is a reinforced concrete slab infill (1953) connecting the stone arch and steel stringer portions to form a larger intersection. A concrete post and pipe railing remains at the face of the steel stringer, and a stone parapet at the face of the arch.

The stone arch has been repeatedly repaired and repointed. Portions of the wing walls, spandrel walls, and parapets that were originally coursed have been replaced with uncoursed field stone.

Historical and Technological Significance: The bridge, which has been significantly altered and lacks integrity, is not individually eligible and does not contribute to the Oxford Industrial Historic District. The historic district's areas of significance include industry, community development, and rail transportation, and primarily focus on the local iron furnace and foundry and its various phases of growth and decline. The older portions of the bridge fall within the district's period of significance (1741-1930), but are not well-preserved. Highway transportation systems are not a major theme of the historic district, and the NJ 31 right-of-way carried by the bridge's steel stringer portion was not developed until 1920. The bridge is not directly related to the town's historic landscape as it grew up around the iron industry. The factories shut down in the 1920s, and the construction of the state highways is not an important story to the impact of the iron industry's decline on the community's development. The bridge is not a contributing resource to the historic district.

Another bridge in the historic district, Washington Avenue over Furnace Brook (2101719, c.1910, Oxford Township), is a well-preserved steel stringer with original lattice railings. It carries the town's historic main thoroughfare over Furnace Brook and is rated a contributing structure.

DESIGNER/PATENT DL&W RR OFFICE OF ENGINEER **BUILDER** SMITH, MCCORMICK CO.

SETTING / CONTEXT The Delaware River Viaduct of the DL&W RR's New Jersey Cutoff crosses a five-lane interstate highway and the Delaware River. The right-of-way is abandoned. It is wide enough for two tracks at this point. Its construction was a major engineering accomplishment, and is a significant element in the development of transportation in northwestern New Jersey. Massive cuts, fills and viaducts were built to eliminate extreme grade changes and curves for trains travelling across New Jersey.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Agreed Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 9-span reinforced concrete viaduct has 7 open-spandrel arch spans. The elliptical arches are supported on hollow piers. There are 8 spandrel arches in the 120' end spans and 10 arches per span over the river (150'per span). The deck is enclosed by a concrete post and metal pipe railing. The nearly complete viaduct is an individually technologically distinguished example of its bridge type, and it is also significant for its historical association with the important NJ Cut-Off of the DL&W RR.

Lefferts, H. Leedom Jr., and Piefer, David R., Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. 1979.

Physical Description: The 9-span reinforced concrete viaduct has 7 open spandrel elliptical arch spans and 2 barrel arch spans at the west end. The 1450' long structure has 5 spans of 150' and 2 spans of 120'. The longer spans have ten spandrel arches per span, but the shorter spans have only eight. The fascias of the bridge are not finely detailed, though the piers have stylized pilasters. The railings are composed of concrete posts and 2-high metal pipe rails, with parapet-enclosed refuge bays at the piers. The ballasted deck no longer carries tracking, and the abandonment of the line has allowed vegetation to grow through the ballast. The concrete is deteriorating in some areas of the bridge due to the lack of maintenance.

Historical and Technological Significance: The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a

whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the old 1851 Warren Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical

connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

The viaduct is also individually eligible, in and of itself, including superstructure, substructure, and right-of-way over the water feature and highways.

SETTING / CONTEXT The bridge is located in a wooded area with working farms and scattered 20th century residences. The structure carries the overgrown right-of-way of the New Jersey Cutoff over a two-lane state route with shoulders. The RR was carried on a high fill at this point between the Delaware River and Paulins Kill Viaducts. The construction of the cut-off was a major engineering accomplishment of its day, which was constructed with major cuts and fills and avoided creating any highway railroad grade crossings along its 28.45 mile length.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94, Letter 03/12/01.

SUMMARY The arch tunnel is of the standard design used by the DL&W RR on the 1908-1911 New Jersey Cut-Off. The reinforced concrete arch is flanked by sloping, skewed wingwalls that retain the fill used to build the right-of-way. The slope descends to just a few feet above the crown of the arch. The NJ Cut-Off is a technologically significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The tunnel arch contributes to the significance of the r-o-w. The structure is not individually eligible for listing in the National Register of Historic Places, but is a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District under Criteria A and C.

Physical Description: The reinforced concrete arch tunnel carries the railroad on a high fill over a two-lane highway. The barrel-arch is flanked by sloping, skewed wingwalls that retain the fill used to create the grade for the New Jersey Cut-Off. The skewed structure spans 44 feet (on skew) and is 227 feet wide. The fill slopes to just a few feet above the crown of the arch at each face. There is no railing at the top of the structure. Several utility lines run under the bridge, supported by brackets attached to its faces and intrados.

Historical and Technological Significance: The New Jersey Cut-Off, of which this arched tunnel is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new

DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the old 1851 Warren Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, according to secondary sources, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span thru-girder bridge bears on scored concrete abutments with sloped wingwalls. The encased floorbeams are framed perpendicular to the girders, which are also encased. The bridge is constructed on a large skew. Beam guiderails cross the bridge inside the girder webs. The bridge is representative example of a common pre-World War II type, and it is not technologically or historically distinguished.

SETTING / CONTEXT The bridge is located in a wooded area with some early- to mid-20th century commercial structures nearby. It is adjacent to structure 2107150, an abandoned RR right-of-way over the same federal highway. The bridge carries an abandoned road over the two-lane highway.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 11/24/92

SUMMARY The skewed four-span bridge is composed of two stringer spans over the roadway and two slab end spans. The encased stringers are supported on eight-column reinforced concrete bents. The abutments are also concrete. The balustrade is a standard State-designed type, with Moderne-styled cornices above the piers at both faces. The bridge is a representative example of a common pre-World War II bridge type, and is not technologically or historically distinguished.

SETTING / CONTEXT The bridge is located in an urban neighborhood of early-20th century dwellings in Phillipsburg. It carries one track in a two-track right-of-way over a two-lane city street with sidewalks. Phillipsburg was forever changed in the 1850s by the entrance of the railroads. In 1855 the Lehigh Valley RR, the third line in Phillipsburg, built a bridge across the Delaware River to Easton.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span deck-girder bridge is seated on high, coursed ashlar abutments with concrete wingwalls. Two pairs of steel girders support open decks. K-bracing is present between the girders that are paired together, but not between the pairs. The span is a well-preserved example of a common bridge type that is extremely well represented in northern New Jersey. It is neither technologically nor historically distinguished, and postdates the historically significant period of railway development.

SETTING / CONTEXT The bridge is located at the southern edge of Phillipsburg. It carries one active track, though it is wide enough for two, and it crosses two two-lane roads and a creek that was part of the Morris Canal. Adjacent to the bridge is Green's Bridge, a five-span ashlar arch structure built in 1865 by the CNJ RR and considered eligible for the NR by NJT. The two bridge decks are approximately the same elevation, about 70' above the creek bed.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Morris Canal. 10/01/1974. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 5-span deck-girder bridge replaced an earlier span carried on ashlar abutments and piers that form part of the substructure for the present superstructure on a slightly realigned r-o-w. The abutments were widened with concrete extensions and new concrete seats were added to the abutments. Pairs of girders are braced with bottom K-bracing and diaphragm bracing. Though a large structure, the 1913 bridge is an example of a common type, and is not technologically nor historically distinctive.

SETTING / CONTEXT The bridge is located in an isolated wooded setting. It carries an unimproved road over a single active track. The line was developed in the 1870s by the Lehigh Valley RR. In 1855 they had crossed the Delaware River at Phillipsburg and then used the CNJ for transportation across New Jersey. In the 1870s it became important for them to have their own line so they built the Easton & Amboy RR to the ports at Perth Amboy. Since 1976 Conrail has owned and operated the line.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span bridge has three span types: a stringer span, a pony truss middle span and a thru-girder span. The abutments are concrete, with built-up steel column-and-lateral-bracing bents. The riveted Warren truss span is built-up from channel and angle sections, plates and lacing. The timber deck is supported on timber stringers throughout the bridge, with rolled floorbeams on the truss and built-up girder span. The bridge is a well-preserved structure, and is a significant example of its type.

INFOR MATION

Bibliography:
NJDOT Plan File. Conrail 0501:70.72.
Snell, James. History of Sussex and Warren Counties, New Jersey. Philadelphia: Everts and Peck, 1881.

Physical Description: The 3-span bridge is composed of a pony truss, a stringer, and a thru girder span supported on ashlar abutments and built up bents set on stone plinths. The main span is a 55'-long 5-panel riveted Warren with verticals pony truss span. The knee braces or outriggers are original, as are the 3-high pipe railings on the inner face of the trusses. The top chord is a built-up box member while the verticals are composed of angle section with both battens and lacing stiffening. The stringers and deck are timber. The built-up thru girder span is topped with pipe railing as is the rolled steel stringer span. The flared steel bents are built-up members with lateral bracing.

Historical and Technological Significance: The 3-span private road railroad overpass bridge erected in 1901 is technologically significant as a well-preserved and documented example of a bridge type commonly used for grade crossing eliminations in central and northern New Jersey (Criterion C). Examples of the same pony truss bridge type over the same rail line are also found in Somerset County (1851160, Farm Road over Conrail (c.1900), Branchburg Township; 1851161, Black Point Road over Conrail (1910), Branchburg Township), but are not considered eligible due to alterations and poor condition. The private road span, identified as being fabricated in iron on the 1900 plans, was designed by the Office of the Engineer of the Easton & Amboy Division of the Lehigh Valley Railroad, an important anthracite hauler that developed its own line across New Jersey to Perth Amboy in the early 1870s. The 1900 bridge was fabricated by the newly formed American Bridge Company. The construction details of the bridge, which is composed of one riveted Warren pony truss span, one built-up plate girder thru girder span, and one steel stringer span supported on ashlar abutments and built-up bents, are typical of the turn-of-the-century period. The knee braces, or outriggers, are an original detail as are the pipe railings. With the exception of 1939 repairs made to the deteriorated sections of the rolled floor beams, the bridge is remarkably complete making it a noteworthy example of ca. 1900 bridge technology.

Boundary Description and Justification: Because the bridge is individually distinguished, the boundary is limited to the superstructure and substructure of the bridge itself.

SETTING / CONTEXT The bridge is located in a wooded, undeveloped area. It carries a two-lane road over the overgrown two-track right-of-way of the Delaware Lackawanna & Western RR's New Jersey Cutoff. The development of the r-o-w straightened the coal-hauling line's route through the state. The project was a major engineering accomplishment for its day, and the route provides a historic context. It is an important element in the transportation history of New Jersey.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Agreed Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span reinforced concrete arch bridge is skewed and has concrete balustrades with oval piercing. It is similar to other deck arch bridges in Warren & Sussex counties that are part of the DL&W RR's New Jersey Cut-Off, an ambitious engineering project undertaken 1908-1911. The route was composed exclusively of 73 reinforced concrete structures. This bridge is significant as part of the historically and technologically important railroad improvement campaign. It is well preserved.

Lefferts, H. Leedom Jr., and Piefer, David R., Northwest New Jersey: An Inventory and History of Historic Engineering and Industry. 1979.

Physical Description: The one-span reinforced concrete deck arch bridge is skewed. The skewback foundations of the structure are set on rock, as the bridge carries a two-lane road over a cut section of the railroad right-of-way. The concrete balustrades are pierced with ovals. The roadway exhibits a vertical crest curve over the elliptical arch bridge. The construction date (1910) is inscribed at the crown of the arch in the western fascia. The right-of-way is overgrown at this point.

Historical and Technological Significance: The New Jersey Cut-Off, of which this deck arch bridge is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information

gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears

to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

CONSULT STATUS Not Individually Eligible. Agreed Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span reinforced-concrete arch bridge on a private road was inaccessible to inspection. Bridge plans show the span to be similar to at least 12 other highway overpasses along the New Jersey Cut-Off. Assuming that field check demonstrates the bridge retains its integrity, it is eligible as a contributing structure to the DL&W's New Jersey Cut-Off right-of-way. The Cut-Off is noted for its early and exclusive use of reinforced concrete structures.

Physical Description: The one-span reinforced concrete deck arch bridge carries an unmaintained private road over a cut section of the railroad right-of-way. The roadway has become overgrown and the bridge is inaccessible, and it was not field inspected. Plans for the bridge show a well-detailed structure with scored spandrels above the elliptical arch. The concrete balustrades have concrete posts framing panels that are pierced with diamond shapes. A concrete rail is also diamond-shaped as it spans the concrete posts above the pierced panels. According to an unnamed person who lives near the structure, the bridge is still in place and has not been altered.

Historical and Technological Significance: The New Jersey Cut-Off, of which this deck arch bridge is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included. The DL&W offered property owners a choice for private farm roads such as this: they could have a bridge built across the right-of-way or they could sell the land on the opposite side of the tracks to the rail company. This bridge is representative of a bridge that was built for an owner who decided to retain his property on both sides of the track.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

SUMMARY The skewed one-span reinforced concrete deck-arch bridge is a high-rise structure on concrete abutments. It has a concrete balustrade with oval piercings typical of many of the New Jersey Cut-Off bridges. The bridge is one of 12 reinforced concrete deck-arch bridges along the 28.5 mile route. Though not individually significant, the bridge contributes to the important railroad-improvement campaign. The cut off is noted for its exclusive use of reinforced concrete for all its structures.

Physical Description: The one-span reinforced concrete elliptical deck arch bridge is skewed. The skewback foundations of the structure are set on rock, as the bridge carries a two-lane road over a cut section of the railroad right-of-way. The concrete balustrades are pierced with ovals, with skewed balustrades at the approaches. The construction date (1910) is inscribed at the crown of the arch in the fascia. The right-of-way is overgrown at this point, and the asphalt-paved deck has vegetation growing along both curblines.

Historical and Technological Significance: The New Jersey Cut-Off, of which this deck arch bridge is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County). From there the coal could be moved eastward to Elizabethport (Union County). In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a

whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed. These structures often supported high fill embankments. Over 35 of these structures were built along the line, according to secondary sources, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. SUMMARY The reinforced concrete elliptical arch bridge is set on high-rise concrete skewbacks. The bridge has diamond-pierced balustrades with a concrete rail above the pierced panels. The bridge is one of twelve of its type built from 1908 to 1911 on the railroad's route. It is significant as a contributing element to the DL&W RR's New Jersey Cut-Off right-of-way, an important railway-improvement campaign noted for its exclusive use of reinforced concrete.

Physical Description: The one-span reinforced concrete deck arch bridge is skewed. The skewback foundations of the structure are set on rock, as the bridge carries a two-lane road over a cut section of the railroad right-of-way. The concrete balustrades have posts framing panels with diamond-shaped piercings. A concrete rail spans between the posts above the panels. The roadway approach has a sharp curve at the north end of the elliptical-shaped deck arch bridge.

Historical and Technological Significance: The New Jersey Cut-Off, of which this deck arch bridge is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information

gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears

to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

SETTING / CONTEXT The bridge is located in an isolated area, and carries an unimproved road that is the driveway to a farm over an abandoned railroad right-of-way. The line is the Delaware Lackawanna & Western Railroad's New Jersey Cut-Off, built 1908-1911. The Cut-Off involved huge amounts of cutting, filling and reinforced concrete bridge construction to eliminate extreme grade changes and limit curves. It was a major engineering accomplishment of its day, and the route provides a historic context.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span reinforced concrete arch bridge sits on high rise concrete skewbacks. The bridge has concrete balustrades typical of oval-pierced balustrades of the cut-off bridges. The structure is one of 12 of its type along the route. It is an example of the railroad's effort to provide access for even minor existing roads over the new r-o-w. The DL&W New Jersey Cut-Off is a historically and technologically important railroad-improvement campaign noted for its use of reinforced concrete.

Physical Description: The one-span reinforced concrete elliptical deck arch bridge is skewed. The skewback foundations of the structure are set on rock, as the bridge carries an unimproved road over a cut section of the railroad right-of-way. The concrete balustrades are pierced with ovals, with skewed sections at the approaches. The construction date (1911) is inscribed at the crown of the arch. The bridge is representative of the DL&W's commitment to provide bridges across their right-of-way for even minor roads and farm roads that existed prior to the line's construction. The right-of-way is now overgrown at this point.

Historical and Technological Significance: The New Jersey Cut-Off, of which this deck arch bridge is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included. The DL&W offered property owners a choice for private farm roads such as this: they could have a bridge built across the right-of-way or they could sell the land on the opposite side of the tracks to the rail company.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new

DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Physical Description: The one-span reinforced concrete elliptical deck arch bridge is skewed. The skewback foundations of the structure are set on rock, as the bridge carries a two-lane road over a shallow cut section of the railroad right-of-way. The concrete balustrades are pierced with ovals, and have skewed sections at the approaches. The roadway curves at the north approach. The construction date (1911) is inscribed in the panel of the balustrade post at the center of the span. The right-of-way is overgrown at this point.

Historical and Technological Significance: The New Jersey Cut-Off, of which this deck arch bridge is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information

gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears

to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.

SETTING / CONTEXT The bridge is located in a wooded area with sparse residential development. The one-lane structure carries a winding road over the abandoned railroad right-of-way that was developed in 1908-1911 by the Delaware Lackawanna & Western RR as the New Jersey Cut-Off, a line built to increase efficiency by decreasing curves and eliminating extreme grade changes. The construction of the DL&W Cut-Off was a major engineering accomplishment of its day, and the route provides a historic context.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Agreed Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span reinforced concrete deck arch bridge is set on high-rise skewbacks. The oval-pierced concrete balustrade follows the vertical crest curve of the roadway over the span. The bridge is one 12 reinforced concrete deck-arch bridges along the 28.5 mile cut-off. Though not individually significant, the bridge contributes to the historically and technologically important railroad-improvement campaign. The cut-off is noted for its exclusive use of concrete for all of its structures.

NJDOT Bridge File: Scranton Branch RR; 62.19.

Physical Description: The one-span reinforced concrete deck arch bridge has skewback foundations set on rock. The bridge carries a two-lane road over a deep cut section of the railroad right-of-way. The concrete balustrades are pierced with ovals, with beam guiderails lining the approaches. The roadway exhibits a vertical crest curve over the elliptical arch bridge. The construction date (1911) is inscribed at the crown of the arch. The right-of-way is overgrown at this point, and the asphalt-paved deck has debris accumulating and vegetation growing along the curblines.

Historical and Technological Significance: The New Jersey Cut-Off, built in 1908-1911, is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The railroad's use of reinforced concrete for all of the structures built along the road did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County). From there the coal could be moved eastward to Elizabethport (Union County). In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a

whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed. These structures often supported high fill embankments. Over 35 of these structures were built along the line, according to secondary sources, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical

connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. SETTING / CONTEXT The bridge, located in an urban area dominated by ca. 1900 residences, carries a two-lane road with sidewalks over one active track. 100' south of the bridge is a 1910 Warren thru truss bridge over CNJ tracks (NJT Raritan Valley Line, MP 72.15) that has been determined eligible. Between the sets of two tracks, a station was built by the DL&W to serve its own line as well as that of the CNJ. The station and the bridges are located approximately 1000' from the Delaware River.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span encased stringer bridge is supported on ashlar abutments and an uncommon pier. The pier is built of steel columns with laced lateral bracing, and a built-up hammerhead steel pier cap. The columns are set in a concrete crash wall. The stringer spans are not of equal length. The deck is enclosed by paneled concrete parapets. The bridge is not technologically distinguished, as it is one of over 65 stringer spans in Warren County.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The four-span multi-deck-girder bridge sits on ashlar and concrete abutments and steel and concrete piers. The bridge was altered in 1944 when the north end of the bridge was widened with concrete tee-beams on a concrete-widened abutment. A bent and two new concrete columns were also added then. The bridge had been previously strengthened with the replacement of a sidewalk stringer with a heavier girder that could support vehicular traffic. The bridge has not retained its design integrity.

SUMMARY The 1-span reinforced concrete T-beam bridge is set on rubble-course abutments with concrete caps. The five precast T-beams are skewed to the abutments. The railing is a self-supporting precast truss-like balustrade set adjacent to the beams on precast seats. The bridge is 1 of 4 similar surviving T-beams built by the DL&W RR in Warren County between 1913 and 1916. The bridges are all significant due to the early use of precast concrete and their historic association with the DL&W RR.

Physical Description: The one-span reinforced concrete T-beam bridge sits on rubble-course abutments with concrete seats. The stone abutments are from an earlier span, with the precast concrete seats being set on flat concrete beds on top of the stone. The superstructure is composed of 5 precast reinforced concrete T-beams. Asphalt covers the deck surface between the precast Warren truss-pattern balustrades. The self-supporting balustrades are set on the bridge seats.

Historical and Technological Significance: The 1916 North Main Street Bridge is an early and technologically significant example of precast concrete T-beam construction. It was built by the Delaware, Lackawanna, and Western Railroad (DL&W) based upon designs of its Bridge Division headed by noted engineer A. Burton Cohen. From 1910 to 1920 Cohen led the DL&W Bridge Division to a national reputation for its innovative use of concrete. In engineering circles the DL&W was known as the "concrete railroad," and it did more than any other railroad to gain the widespread acceptance of concrete for long-span structures. The bridge is eligible under National Register Criteria A and C as a well-preserved example of a technologically significant bridge type and for its historical association with Cohen and the DL&W. The bridge is one of four similar precast T-beam bridges (1913-1916) over the DL&W's Washington Secondary in Warren County (2154162, 2154163, 2154165, 2154169). The bridges are all well-preserved and technologically and historically significant as the only surviving examples of their type known to exist in New Jersey.

Reinforced concrete was used mostly for small slab and deck arch spans in the 1910s, but Cohen and the DL&W tried something more aggressive with T-beam construction. The T-beam is a more efficient use of material than a slab bridge of equal length. From 1913 to 1916 they built concrete T-beam highway overpasses on the DL&W's Washington Secondary. The span of the overpasses ranged from over 30' to 37' at a time when it was unusual to build even conventional reinforced-concrete T-beam or slab bridges of that length. The beams weighed each about 14 tons, significantly less than modern precast beams, but were easily transported and functional for light highway traffic. No records have been located that specifically address the DL&W's fabrication of these spans, and it is unknown whether any others were built on former DL&W properties. Articles from the Engineering News-Record demonstrate that other railroads did not begin to build precast concrete bridges of similar span until the mid-1920s, further indicating the DL&W's advanced use of the technology. Precast concrete beam spans eventually became one of the most prevalent post-WWII highway bridge types, and the DL&W's T-beam bridges are historically significant precursors of the modern approach to bridge building.

Another precast bridge from the same period over the same rail line also illustrates the DL&W's leadership in working with reinforced concrete. 2154168 is a 2-span precast slab bridge built in 1913 that is the documented example of its type in the state.

The DL&W, composed of a network of smaller railroads in Pennsylvania, New York, and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. In reaching to the east, in 1868 the DL&W acquired the Morris and Essex Railroad, which from 1830 to 1860 built a line from Hoboken to Phillipsburg. The line spanned by the precast T-beam spans was developed around 1860 by the Morris and Essex Railroad, which at the time was extending its tracks from Hackettstown to Phillipsburg.

The DL&W's reputation for reinforced-concrete bridge designs began in 1908 the company made engineering headlines with its decision to build a whole new line across northwestern New Jersey. The plan, known as the New Jersey Cut-Off, achieved minimum grades and

curves with massive cuts and fills and several impressively large reinforced-concrete arch viaducts. The exclusive use of reinforced concrete for all the structures along the New Jersey Cut-Off, like 2114159, was a pioneering action and set the stage for the DL&W's continued experimentation with concrete bridges.

Engineer A. Burton Cohen rose to Chief Engineer of the DL&W's Bridge Division in 1910 and designed numerous bridges for the railroad including the Tunkhannock Viaduct (1915) in Nicholson, Pennsylvania, the largest reinforced-concrete arch structure in the world. The plans for the precast T-beam bridges in Warren County were signed by Cohen as the Chief Engineer. After 1920 Cohen went into private practice continuing his specialty in reinforced-concrete structures. In New Jersey he was responsible for the 1926 open spandrel arch bridge at Journal Square in Jersey City (0900008). In 1927 the American Concrete Institute awarded Cohen a gold medal for his solutions to bridge problems "with economy as well as architectural merit."

Three of the four remaining precast concrete T-beam spans are in public use, while one (2154169) services a farm road. Conrail records indicate that two other precast T-beam bridges spanned the DL&W's Washington Secondary, but they have been replaced within the last five years.

Boundary Description and Justification: Because it is the precast technology of the span that is significant, the boundary is limited to the superstructure and the abutments. Though the railroad right-of-way has several precast bridges, they are not used exclusively. There other common-type overpasses along the line which is one of many crossing northern New Jersey. Thus the railroad route itself is not technologically significant; only some structures are.

SETTING / CONTEXT The bridge is located in a wooded area with a modern residence on an adjacent property. The one-lane structure carries a winding road over one track in a two-track wide right-of-way. The railroad line was developed by the Morris & Essex Railroad around 1860. Their lines reached only as far west as Hackettstown, so they constructed this extension to the Delaware River at Phillipsburg. The DL&W RR took over in 1868, connecting their Warren RR to the M&E in Washington.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible. Delaware, Lackawanna & Western Railroad Old Main Line Historic District. Contributed.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span concrete tee-beam bridge sits on rubble-course abutments with concrete caps. The four precast beams form the deck of the span and are flanked by self-supporting precast balustrades that also rest on precast bridge seats. The span is one of six built between 1913-1916), though only four remain. All are significant due to their age, completeness, and extensive and innovative use of precast concrete by the Delaware, Lackawanna & Western Railroad.

Schruffer, LeRoy M. "Casting Concrete-Slab Bridges for the Pennsylvania Railroad," Engineering News, Vol. 74,3 (July 15, 1915).

Physical Description: The one-span, precast, reinforced concrete T-beam bridge sits on rubble-course abutments with concrete seats. The stone abutments are from an earlier span, with the precast concrete seats being set on flat concrete beds on top of the stone. The superstructure is composed of 4 precast reinforced concrete T-beams. Asphalt covers the deck surface between the precast Warren truss-pattern balustrades. The self-supporting balustrades are set on the bridge seats.

Historical and Technological Significance: The precast 1916 T-beam Buttermilk Bridge Road bridge is an early example of its type and of a technology that is still used in concrete construction (Criteria A. C.). It was built by the Delaware, Lackawanna, and Western Railroad (DL&W) based upon designs of its Bridge Division headed by noted engineer A. Burton Cohen. From 1910 to 1920 Cohen led the DL&W Bridge Division to a national reputation for its innovative use of concrete. In engineering circles the DL&W was known as the "concrete railroad," and it did more than any other railroad to gain the widespread acceptance of concrete for long-span structures. The bridge is one of four similar precast T-beam bridges built between 1913 and 1916) over the DL&W's Washington Secondary in Warren County (2154162, North Main Street, Greenwich Twp.; 2154165 Brick Yard Road, Mansfield Twp.; 2154169 in Mansfield Twp.). The precast T-beam bridges are all well-preserved and technologically and historically significant as the only surviving 1910s examples of their type documented in New Jersey.

Reinforced concrete was used mostly for small slab and deck arch spans in the 1910s, but Cohen and the DL&W tried something more aggressive with T-beam construction. The T-beam is a more efficient use of material than a slab bridge of equal length. From 1913 to 1916 they built concrete T-beam highway overpasses on the DL&W's Washington Secondary. The span of the overpasses ranged from over 30' to 37' at a time when it was unusual to build even conventional reinforced-concrete T-beam or slab bridges of that length. The beams weighed each about 14 tons, significantly less than modern precast beams, but were easily transported and functional for light highway traffic. No records have been located that specifically address the DL&W's fabrication of these spans, and it is unknown whether any others were built on former DL&W properties. Articles from the Engineering News-Record demonstrate that other railroads did not begin to build precast concrete bridges of similar span until the mid-1920s, further indicating the DL&W's advanced use of the technology. Precast concrete beam spans eventually became one of the most prevalent post-WWII highway bridge types, and the DL&W's T-beam bridges are historically significant precursors of the modern approach to bridge building.

Another precast bridge from the same period over the same rail line also illustrates the DL&W's leadership in working with reinforced concrete. 2154168 is a 2-span precast slab bridge built in 1913 that is the documented example of its type in the state.

The DL&W, composed of a network of smaller railroads in Pennsylvania, New York, and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. In reaching to the east, in 1868 the DL&W acquired the Morris and Essex Railroad, which from 1830 to 1860 built a line from Hoboken to Phillipsburg. The line spanned by the precast T-beam spans was developed around 1860 by the Morris and Essex Railroad, which at the time was extending its tracks from Hackettstown to Phillipsburg.

The DL&W's reputation for reinforced-concrete bridge designs began in 1908 the company made engineering headlines with its decision to build a whole new line across northwestern New Jersey. The plan, known as the New Jersey Cut-Off, achieved minimum grades and curves with massive cuts and fills and several impressively large reinforced-concrete arch viaducts. The exclusive use of reinforced

concrete for all the structures along the New Jersey Cut-Off, like 2114159, was a pioneering action and set the stage for the DL&W's continued experimentation with concrete bridges.

Engineer A. Burton Cohen rose to Chief Engineer of the DL&W's Bridge Division in 1910 and designed numerous bridges for the railroad including the Tunkhannock Viaduct (1915) in Nicholson, Pennsylvania, the largest reinforced-concrete arch structure in the world. The plans for the precast T-beam bridges in Warren County were signed by Cohen as the Chief Engineer. After 1920 Cohen went into private practice continuing his specialty in reinforced-concrete structures. In New Jersey he was responsible for the 1926 open spandrel arch bridge at Journal Square in Jersey City (0900008). In 1927 the American Concrete Institute awarded Cohen a gold medal for his solutions to bridge problems "with economy as well as architectural merit."

Three of the four remaining precast concrete T-beam spans are in public use, while one (2154169) services a farm road. Conrail records indicate that two other precast T-beam bridges spanned the DL&W's Washington Secondary, but they have been replaced within the last five years.

Boundary Description and Justification: Because it is the precast technology of the span that is significant, the boundary is limited to the superstructure and the abutments. Though the railroad right-of-way has several precast bridges, they are not used exclusively. There other common-type overpasses along the line which is one of many crossing northern New Jersey. Thus the railroad route itself is not technologically significant; only some structures are.

Physical Description: The one-span reinforced concrete T-beam bridge sits on rubble-course abutments with concrete seats. The stone abutments are from an earlier span, with the precast concrete seats being set on flat concrete beds on top of the stone. The superstructure is composed of 3 precast reinforced concrete T-beams. The top of the T-beams forms the deck and wearing surface of the bridge between the precast truss-like balustrades. The self-supporting balustrades are also set on the bridge seats.

Historical and Technological Significance: The precast 1913 T-beam Brick Yard Road bridge is an early example of its type and of a technology that is still used in concrete construction (Criteria A. C.). It was built by the Delaware, Lackawanna, and Western Railroad (DL&W) based upon designs of its Bridge Division headed by noted engineer A. Burton Cohen. From 1910 to 1920 Cohen led the DL&W Bridge Division to a national reputation for its innovative use of concrete. In engineering circles the DL&W was known as the "concrete railroad," and it did more than any other railroad to gain the widespread acceptance of concrete for long-span structures. The bridge is one of four similar precast T-beam bridges built between 1913 and 1916) over the DL&W's Washington Secondary in Warren County (2154162, North Main Street, Greenwich Twp.; 2154163, Buttermilk Bridge Road, Washington Twp.; 2154165 Brick Yard Road, Mansfield Twp.; and, 2154169, Dirt Road, Mansfield Twp.). The precast T-beam bridges are all well-preserved and technologically and historically significant as the only surviving 1910s examples of their type documented in New Jersey.

Reinforced concrete was used mostly for small slab and deck arch spans in the 1910s, but Cohen and the DL&W tried something more aggressive with T-beam construction. SETTING / CONTEXT The bridge is located at the south edge of the village of Port Murray. The village was built along the Morris Canal, with late-19th and 20th century residences dominant. The bridge carries a two-lane county route over one active track in a two-track width right-of-way. An abandoned railroad station with grain hoppers is located a few hundred feet northeast. The bridge is at a boundary (DL & W RR r-o-w) of a historic district.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Listed. Port Murray Historic District. 06/07/1996. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The skewed one-span thru-girder bridge sits on earlier ashlar abutments with concrete seats and widening. The bottom flanges of the built-up girders are encased, as are the floorbeams. Pipe railings are fixed to the top of the girders. The deck is covered with brick pavers. The structure is a representative example of a common bridge type, and it is not individually technologically or historically distinguished. It is located on the boundary of the potential Port Murray Historic District and was built within its period of significance. The bridge is a contributing resource to the historic district. The nomination lists an incorrect date of construction for the bridge.

SETTING / CONTEXT The bridge is located on a farm with cattle and corn fields. The one-lane bridge carries an unimproved private farm road over one active track in a two-track right-of-way. The rail line was developed by the Morris & Essex Railroad around 1860 as they extended their lines beyond Hackettstown to the Delaware River at Phillipsburg. The DL&W RR leased the M&E in 1868, allowing them access to the New York ports after connecting their Warren RR to the M&E lines in Washington.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Delaware, Lackawanna & Western Railroad Old Main Line Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 09/24/96, Letter 6/30/95 03/12/01.

SUMMARY The one-span Warren pony truss is supported by ashlar abutments with concrete seats. The rivet-connected trusses have not been altered since the trusses were moved from Clark's Summit, PA, where they had been used for a highway bridge over DL&W trackage. The bottom chord is encased, as are the floorbeams, which directly support the slab deck. The structure is significant as a well-preserved example of its type, and is one of 4 rivet-connected Warren pony trusses in the county.

INFOR MATION

Bibliography:
NJDOT. Conrail Bridge Plan File.
Snell, James. History of Sussex and Warren Counties, New Jersey. Philadelphia: Everts and Peck, 1881.

Physical Description: The bridge is a 4-panel riveted Warren with verticals pony truss on an ashlar substructure with concrete extensions and bridge seats. It is composed almost entirely of tow-out angle section with plate set between the back-to-back members at the panel points. The inclined end posts have cover plates. The verticals are braced, and a railing is set inside the truss lines at mid-height. What is unusual about the bridge is that the bottom chord and lower panel points, floor beams, and stringers are encased in concrete, and they directly support a concrete deck. There is some impact damage that compromises the structural integrity of the span.

Historical and Technological Significance: The 56'-long riveted Warren pony truss bridge was installed at this farm crossing in 1914 and is significant not so much for being a well-preserved example of its type but because its flooring system reflects the Delaware Lackawanna & Western Railroad's innovative use of concrete as applied to bridge construction (Criterion C). Plans indicate that the trusses, which in style date from c.1900, were moved from a highway crossing east of Clark's Summit, Pennsylvania to the Port Murray area farm crossing. At that time the existing stone abutments of a prior bridge were "torn down until thoroughly good foundation" was obtained for new concrete bridge seats. The trusses were installed, and the floor beams and stringers were encased in poured-in-place concrete, and the concrete deck was poured directly on them. No other truss bridges with encased flooring systems of this type were evaluated by the Historic Bridge Survey. The span is technologically distinguished and valuable as part of the documentation in the DL&W's experimental and innovative application of concrete to a variety of structures related to the operation of their line.

The bridge carries a farm road over what was the Morris & Essex Railroad, an ambitious but not wholly successful east-west line that was acquired by the DL&W about 1870. Its original circuitous right-of-way was bypassed by the 1909-1911 New Jersey Cut-Off, which had several innovative long-span concrete bridges. This section of the Morris and Essex line known as the Washington Secondary connected Washington with Phillipsburg.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including superstructure, substructure, and right-of-way over the rail line.

CONSULT STATUS Individually Eligible. Delaware, Lackawanna & Western Railroad Old Main Line Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 09/24/96, Letter 6/30/95 03/12/01.

SUMMARY The two-span precast concrete slab bridge sits on ashlar abutments with precast bridge seats and a precast pier. The structure is a design of six slab panels simply-supported, using as many precast pieces as possible. The bottom beam of the pier and the curb of the deck were cast in place. The bridge is an early significant example of precast concrete technology and represents the DL&W's innovative use of concrete in the 1910s. It is the only known example of its type and age in New Jersey.

Schruffer, LeRoy M. "Casting Concrete-Slab Bridges for the Pennsylvania Railroad," Engineering News, Vol. 74,3 (July 15, 1915).

Physical Description: The two-span precast reinforced concrete slab bridge sits on ashlar abutments with concrete seats and a concrete pier. The stone abutments are from an earlier span, with the precast concrete seats being set on flat concrete beds on top of the stone. The pier is composed of precast columns set on a cast-in-place plinth. A precast cap crosses the columns below the slabs. The superstructure is composed of 6 precast reinforced concrete slabs. The slabs are not covered, but are framed by cast-in-place curbs and metal pipe railings.

Historical and Technological Significance: The 1913 bridge is an early and technologically significant example of precast slab construction. It was built by the Delaware, Lackawanna, and Western Railroad (DL&W) based upon designs of its Bridge Division headed by noted engineer A. Burton Cohen. From 1910 to 1920 Cohen led the DL&W Bridge Division to a national reputation for its innovative use of concrete. In engineering circles the DL&W was known as the "concrete railroad," and it did more than any other railroad to gain the widespread acceptance of concrete for long-span structures. The bridge is eligible under National Register Criteria A and C as a well-preserved example of a technologically significant bridge type and for its historical association with Cohen and the DL&W. The bridge is the only documented 1910s precast concrete slab bridge in the state. The same railroad line, the Washington Secondary, has four other related 1913-1916 precast concrete T-beam bridges (2154162, North Main Street, Greenwich Twp.; 2154163, Buttermilk Bridge Road, Washington Twp.; 2154165 Brick Yard Road, Mansfield Twp.; and, 2154169, Dirt Road, Mansfield Twp.).

Early precast concrete bridges were mostly short-span slab and deck arch designs. The 1913 slab bridge with two 23-1/2' spans is an early attempt at precast concrete slab construction, and was an ambitious length for its time. The six precast slab panels weighed significantly less than modern precast slabs, but were easily transported and functional for light highway traffic. No records have been located that specifically address the DL&W's fabrication of this span, and it is unknown whether any other precast slab spans were built on former DL&W properties. Articles from the Engineering News-Record demonstrate that other railroads did not begin to build precast concrete bridges of similar span until the mid-1920s, further indicating the DL&W's advanced use of the technology. Precast concrete slab spans eventually became an important post-WWII highway bridge type, and the DL&W's precast slab bridge is a historically significant precursor of the modern approach to bridge building.

The DL&W, composed of a network of smaller railroads in Pennsylvania, New York, and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. In reaching to the east, in 1868 the DL&W acquired the Morris and Essex Railroad, which from 1830 to 1860 built a line from Hoboken to Phillipsburg. The line spanned by the precast slab and T-beam spans was developed around 1860 by the Morris and Essex Railroad, which at the time was extending its tracks from Hackettstown to Phillipsburg.

The DL&W's reputation for reinforced-concrete bridge designs began in 1908 when the company made engineering headlines with its decision to build a whole new line across northwestern New Jersey. The plan, known as the New Jersey Cut-Off, achieved minimum grades and curves with massive cuts and fills and several impressively large reinforced-concrete arch viaducts. The exclusive use of reinforced concrete for all the structures along the Cut-Off was a pioneering action and set the stage for the DL&W's continued experimentation with concrete bridges.

plans for the precast slab bridge and the four precast concrete T-beam bridges in Warren County was signed by Cohen as the Chief Engineer. After 1920 Cohen went into private practice continuing his specialty in reinforced-concrete structures. In New Jersey he was responsible for the 1926 open spandrel arch bridge at Journal Square in Jersey City (0900008). In 1927 the American Concrete Institute awarded Cohen a gold medal for his solutions to bridge problems "with economy as well as architectural merit."

Boundary Description and Justification: Because it is the precast technology of the span that is significant, and the technology of the route as a whole, the boundary is limited to the superstructure and the abutments.

DESIGNER/PATENT DL&W RR OFFICE OF ENGINEER **BUILDER**

SETTING / CONTEXT The bridge is surrounded by cultivated fields. It carries a private, unimproved farm road over one active track in a two-track wide right-of-way. The line was developed from Hackettstown to Phillipsburg by the Morris and Essex Railroad around 1860. The Delaware Lackawanna & Western RR leased the M&E in 1868, connecting their own Warren RR to it in Washington. The acquisition of the M&E provided the DL&W with their own access to the New York ports.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Delaware, Lackawanna & Western Railroad Old Main Line Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 09/24/96, Letter 6/30/95 03/12/01.

SUMMARY The one-span precast concrete T-beam bridge is set on ashlar abutments with precast bridge seats. The deck of the bridge is formed by the T-beams, with distinctive precast truss-like balustrades at each face. The use of precast concrete is prevalent on this line from 1913-1916, when 6 precast and one precast slab bridges were built. Four T-beams and the slab span survive. This bridge, like the others, is significant due to its early and innovative use of precast concrete bridge members.

Schruffer, LeRoy M. "Casting Concrete-Slab Bridges for the Pennsylvania Railroad," Engineering News, Vol. 74,3 (July 15, 1915).

Physical Description: The one-span reinforced concrete T-beam bridge sits on rubble-course abutments with concrete seats. The stone abutments are from an earlier span, with the precast concrete seats being set on flat concrete beds on top of the stone. The superstructure is composed of 3 precast reinforced concrete T-beams. The deck surface is formed by the tops of the beams on the unimproved and overgrown private road. The precast Warren truss-pattern balustrades are self-supporting, and are set on the bridge seats beside the fascia beams.

Historical and Technological Significance: The precast 1913 T-beam farm road bridge is an early example of its type and of a technology that is still used in concrete construction (Criteria A. C.). It was built by the Delaware, Lackawanna, and Western Railroad (DL&W) based upon designs of its Bridge Division headed by noted engineer A. Burton Cohen. From 1910 to 1920 Cohen led the DL&W Bridge Division to a national reputation for its innovative use of concrete. In engineering circles the DL&W was known as the "concrete railroad," and it did more than any other railroad to gain the widespread acceptance of concrete for long-span structures. The bridge is one of four similar precast T-beam bridges built between 1913 and 1916) over the DL&W's Washington Secondary in Warren County (2154162, North Main Street, Greenwich Twp.; 2154163, Buttermilk Bridge Road, Washington Twp.; 2154165 Brick Yard Road, Mansfield Twp.; and, 2154165 in Mansfield Twp.). The precast T-beam bridges are all well-preserved and technologically and historically significant as the only surviving 1910s examples of their type documented in New Jersey.

Reinforced concrete was used mostly for small slab and deck arch spans in the 1910s, but Cohen and the DL&W tried something more aggressive with T-beam construction. The T-beam is a more efficient use of material than a slab bridge of equal length. From 1913 to 1916 they built concrete T-beam highway overpasses on the DL&W's Washington Secondary. The span of the overpasses ranged from over 30' to 37' at a time when it was unusual to build even conventional reinforced-concrete T-beam or slab bridges of that length. The beams weighed each about 14 tons, significantly less than modern precast beams, but were easily transported and functional for light highway traffic. No records have been located that specifically address the DL&W's fabrication of these spans, and it is unknown whether any others were built on former DL&W properties. Articles from the Engineering News-Record demonstrate that other railroads did not begin to build precast concrete bridges of similar span until the mid-1920s, further indicating the DL&W's advanced use of the technology. Precast concrete beam spans eventually became one of the most prevalent post-WWII highway bridge types, and the DL&W's T-beam bridges are historically significant precursors of the modern approach to bridge building.

Another precast bridge from the same period over the same rail line also illustrates the DL&W's leadership in working with reinforced concrete. 2154168 is a 2-span precast slab bridge built in 1913 that is the documented example of its type in the state.

The DL&W, composed of a network of smaller railroads in Pennsylvania, New York, and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. In reaching to the east, in 1868 the DL&W acquired the Morris and Essex Railroad, which from 1830 to 1860 built a line from Hoboken to Phillipsburg. The line spanned by the precast T-beam spans was developed around 1860 by the Morris and Essex Railroad, which at the time was extending its tracks from Hackettstown to Phillipsburg.

The DL&W's reputation for reinforced-concrete bridge designs began in 1908 the company made engineering headlines with its decision to build a whole new line across northwestern New Jersey. The plan, known as the New Jersey Cut-Off, achieved minimum grades and

A. G. Lichtenstein & Associates, Inc. performed initial survery.

November 12, 2002

curves with massive cuts and fills and several impressively large reinforced-concrete arch viaducts. The exclusive use of reinforced concrete for all the structures along the New Jersey Cut-Off, like 2114159, was a pioneering action and set the stage for the DL&W's continued experimentation with concrete bridges.

Engineer A. Burton Cohen rose to Chief Engineer of the DL&W's Bridge Division in 1910 and designed numerous bridges for the railroad including the Tunkhannock Viaduct (1915) in Nicholson, Pennsylvania, the largest reinforced-concrete arch structure in the world. The plans for the precast T-beam bridges in Warren County were signed by Cohen as the Chief Engineer. After 1920 Cohen went into private practice continuing his specialty in reinforced-concrete structures. In New Jersey he was responsible for the 1926 open spandrel arch bridge at Journal Square in Jersey City (0900008). In 1927 the American Concrete Institute awarded Cohen a gold medal for his solutions to bridge problems "with economy as well as architectural merit."

Three of the four remaining precast concrete T-beam spans are in public use, while one (2154169) services a farm road. Conrail records indicate that two other precast T-beam bridges spanned the DL&W's Washington Secondary, but they have been replaced within the last five years.

Boundary Description and Justification: Because it is the precast technology of the span that is significant, the boundary is limited to the superstructure and the abutments. Though the railroad right-of-way has several precast bridges, they are not used exclusively. There other common-type overpasses along the line which is one of many crossing northern New Jersey. Thus the railroad route itself is not technologically significant; only some structures are.

SETTING / CONTEXT The bridge is located on the driveway of a horse farm. The one-lane structure crosses an inactive railroad line with one track remaining in the right-of-way. This line was developed in the early 1850s by the Central RR of New Jersey. It reached from the New York ports to the Delaware River at Phillipsburg where it connected with other railroads and canals, with its primary purpose hauling coal to the ports. In 1976 the bankrupt line was divided between Amtrak and NJT.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Central Railroad of NJ Main Line Corridor. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95 11/22/95. DOE 11/30/95.

SUMMARY The ca. 1890 lattice-web thru-girders sit on stone abutments (inscribed 1907) with timber seats. The girders were most likely moved to this location some time in the 20th century. The lattice is formed by the crossing of rolled T-sections and flat bars between built-up flanges. Rolled floorbeams are hung from the bottom flanges, and they support timber stringers and the plank deck. This is one of less than 5 remaining lattice girders identified in the state, and it is a well-preserved.

INFOR MATION

Bibliography:

Anderson, Elaine. The Central Railroad of New Jersey's First 100 Years. Easton, PA: 1984.
NJDOT. Conrail Bridge File.
New Jersey Transit. NJT Historic Railroad Bridge Survey. 1991.
Phoenix Bridge Company Records. Bridge Order Books. Hagley Museum and Library.
Snell, James. History of Sussex and Warren Counties, New Jersey. Philadelphia: 1881.

Physical Description: The 40'-long thru girder bridge incorporates iron lattice web girders that appear to have been modified for service at this crossing. The top and bottom flanges are built-up of angle and plate, and the diagonals are t-sections and flat bars. The only verticals are at the end of the girders. Rolled floor beams that extend beyond the girders have been hung from the bottom flanges with carriage bolts. The arrangement does not look original. The stringers and deck are timber. The girders are supported on ashlar abutments inscribed "1907". The seat is narrower than the present span, which bears on timber cribbing. There is no scaring on the top flanges to suggest that these girders were once deck girders.

Historical and Technological Significance: Although no bridge plans to indicate date of fabrication or moving to this site have been located, even undocumented the Central Railroad of New Jersey's wrought iron lattice web girder bridge at a farm crossing is technologically significant as a rare survivor of an early bridge type (Criterion C). The lattice webbing on the Welsh Spur Road bridge is similar in style and construction to a bridge over the same line at milepoint 53.38 in Hunterdon County. That span is included in the NJT 1990-1991 bridge survey, and it is given a date of 1891, but no documentation for the source of the date nor the name of the fabricator is identified on their survey form. The span is also similar to two ca. 1890 lattice web deck girders in Hudson County. Both Bergen Avenue over Conrail in Jersey City (0900011) and Ocean Avenue over Conrail in Jersey City were built by the Central Railroad of New Jersey over its Newark and New York branch. All four bridges have the T-section diagonals and all four are iron. According to Phoenix Bridge Company records at the Hagley Museum and Library, the Central Railroad of New Jersey purchased several lattice through girder spans for unspecified locations in the 1880s and 1890s. The bridge company manufactured the lattice through girder bridge type from the 1870s until about 1900 for both highway and railroad use.

It is likely that the Welsh Spur Road girders are not original to the crossing. The span rests on timber cribbing, and it appears to be wider than the seat notches in the ashlar abutments that are inscribed 1907. There are several instances of earlier trusses being moved to farm crossings such as this one, so historic precedent and physical evidence support the contention that the early girders were moved to this site after 1907. The Central New Jersey originally developed the right-of-way through Warren County in the early 1850s.

Boundary Description and Justification. The bridge is individually eligible, in and of itself, including superstructure, substructure, and right-of-way over the rail line.

SETTING / CONTEXT The bridge is located in a wooded area, at the end of a paved road lined with 19th and 20th century residences. The road continues unimproved, over the span and further into the woods. The structure crosses one track in an abandoned right-of-way of the CNJ RR wide enough for two tracks. The railroad was developed here in the early 1850s for the transfer of the eastern Pennsylvania coal to the New York ports. It is now used mostly for passenger trains and now belongs to NJT and Amtrak.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible. Central Railroad of NJ Main Line Corridor. Contributed.

CONSULT DOCUMENTS SHPO Letter 6/30/95 11/22/95. DOE 11/30/95.

SUMMARY The one-span riveted double-intersection Warren thru-truss bridge sits on stone abutments. The members of the truss are virtually unaltered with the exception of impact damage. One of the verticals is severely twisted and an adjacent diagonal is also bent. The truss is built-up using channel and angle sections, lacing bars and cover plates. The floorbeam-stringer floor system was strengthened in 1914 and 1941. The bridge is well-preserved, and is one of two examples of its type in Warren County.

INFOR MATION

Bibliography:
Condit, Carl. American Building Art 19th Century. New York: 1960.
Darnell, Victor. Directory of American Bridge Building Companies 1840-1900. Washington, D.C.: Society for Industrial Archeology, 1984.
Snell, James. History of Sussex and Warren County New Jersey. Philadelphia, 1881.
NJDOT: Bridge Plan File; Raritan Valley Ln, 66.51.

Physical Description: The bridge is a 6-panel rivet-connected double-intersection Warren thru truss. The top chord and inclined end posts are composed of toe-out channel joined on both the top and bottom face with lacing. The bottom chord is made up of angles linked by a laced web. The compression diagonals are also laced angles while the tensile members are one of two types; angles with battens or angles with lacing. Each panel is subdivided with a subtie carrying floor beams. The portal braces have lattice infill, and the lateral bracing and sway bracing are original. There was no original railing on the inner faces of the trusses. The 10'-5" wide bridge has rolled floor beams that have been strengthened and carries a wood plank deck.

Historical and Technological Significance: The 1898 6-panel riveted construction double-intersection Warren thru truss bridge with subdivided panels is technologically significant as a rare survivor of an uncommon truss type. It also has unusual construction details (Criterion C). According to plans, the bridge was designed by the Central Railroad of New Jersey (CNJ) and fabricated by the Passaic Rolling Mill of Paterson. Although the capacity has been reduced due to deterioration and impact damage, the bridge is otherwise unaltered adding to its technological distinction. The top chord of toe-out channel with top and bottom lacing is an unusual detail. The Warren truss, which is distinguished by members designed to carry both tensile and compressive forces, was developed in 1846 by British engineers, but did not become popular until the 1890s when a successful means of performing field rivets became available. The double intersection Warren thru truss, a variation on the standard Warren truss design, was not an uncommon bridge type from the 1890s into the first decade of the 20th century and a small handful survive in New Jersey including Buttzville Road over Pequest River (2102307, 1902, White Township), also evaluated as significant.

The Passaic Rolling Mill, fabricator of the span, was established in Paterson in 1877, and in 1884, its fabricating capacity was 12,000 tons, making it one of the largest works in the country at that time. They produced structural steel as well as bridge components. The Central Railroad of New Jersey was the first railroad in Warren County, and its importance is linked to the fact that it provided access across New Jersey with the coal-rich Lehigh Valley region of Pennsylvania. This right-of-way was part of the 1847-chartered extension to Easton of the Elizabeth and Somerville Railroad. The extension was known as the Somerville and Easton Railroad, and in 1850, the two companies were merged and restyled the Central Railroad of New Jersey. The line to Easton was completed in 1852, and it served as the route that the Lehigh Valley Railroad also crossed to Jersey City until the LVRR completed its own route in the early 1870s. It is not known if this is the first span to eliminate the grade crossing at Springtown, as the area was then known.

The flooring system was strengthened in 1914 and 1941 with the addition of angles and/or plates to the floor beams. The bridge now services an unimproved road.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including superstructure, substructure, and right-of-way over the rail line.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span steel stringer rests on reinforced concrete abutments and wingwalls, which are adjacent to the parallel railroad bridge. There are about 8 feet between the two superstructures. The bridge was widened from 36' to 46' in 1967, and the new stringers are supported on concrete abutment extensions. The reinforced concrete and pipe parapets also date to 1967. The bridge is not technologically or historically distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries two-lanes of traffic across the Delaware and Raritan Canal in the industrial village of South Bound Brook. The canal, which was built in the 1830s to carry barges from New Brunswick to Trenton, parallels the Raritan River along this portion of its route. The bridge is just downstream from a restored lock. South of the bridge is a brick factory complex (c.1880-1920). The Delaware and Raritan Canal R-O-W is a National Register Listed property (5/11/73).

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. D&R Canal. 05/11/1973. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bobtail, deck girder, center-bearing swing span is one of six movable bridges across the Delaware and Raritan Canal. Constructed in 1920 for the PA RR late in the operation of the canal, the bridge retains its operating machinery, but it is sealed. The bridge employs representative swing span technology, and although no longer operable has not been significantly altered. The bridge is a contributing element to the D & R Canal whose right-of-way is NR-listed. No original plans are available.

INFOR MATION

Bibliography:

McKelvey, William. Delaware & Raritan Canal A Pictorial History. 1975.
NJDOT. Plan File: 3000168.

Physical Description: The single-span bobtail center-bearing swing span bridge has a long end of approximately 51' and a tail end of 35'. The span with a 24' roadway has built-up girders placed 10' apart with the rest of the structure supported on built-up brackets. The abutments and swing pier are concrete. The floor beams, stringers, three-rail high railings, and open grid steel deck were installed in 1978. The operating mechanism with its sets of reduction gears that activate the drive pinion and electric motors remain in place under the girder, but they have not been maintained. The concrete counterweight is also still in place. The bridge has welded elements locking it in the closed position at both the heel and toe ends. The tender's shanty and controls have been removed.

Historical and Technological Significance: The bobtail center-bearing swing span deck girder bridge was built in 1920 by the Pennsylvania Railroad, and while not contemporary with the heyday of the canal, is the largest and most complete of the extant moveable bridges to cross the National Register-listed Delaware and Raritan Canal right-of-way. The canal, which runs from Bordentown to New Brunswick, was completed in 1834, and it served as an important transportation route for coal from eastern Pennsylvania bound for the New York market. The Pennsylvania Railroad acquired the canal in 1871 when it leased the United New Jersey and Rail Company in order to get that company's rail routes to New York City. The PA RR did not emphasize the canal aspect of the operation. Marine-borne freight dropped dramatically so that by World War I there was little commercial traffic on the canal. In 1924 there were only two mule-drawn boat captains remaining.

Regardless of how little traffic existed, the railroad was responsible for maintaining the bridges that crossed the canal. In 1920 the Pennsylvania Railroad replaced the swing span that carried Main Street over the canal with a built-up deck girder bobtail swing span. No original plans or construction records for the bridge remain with any state agency. It is assumed, based on the history of other bridges, that the span was designed by the PA RR Office of Chief Engineer. The bridge is not operable; it was fixed in the late 1960s, and while the operating mechanism remains in place, it has not been maintained and the source of power and operator's controls and shanty have been removed.

The bridge crosses the historic right-of-way of the Delaware & Raritan Canal, and while it was built before the canal was abandoned by the PA RR in 1933, it is not associated historically with the heyday of canal operations. The bridge is a good representative example of a bobtail swing span, and it remains one of the largest formerly moveable spans over the canal and is thus both historically and technologically noteworthy (criteria A, C).

Boundary Description & Justification: The bridge crosses the National Register-listed right-of-way of the Delaware & Raritan Canal. That nomination did no address structures related to or crossing the right-of-way. This bridge is significant because of its type and history. The span itself and the limits of the canal right-of-way are evaluated as significant.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge carries a two lane road and a sidewalk over the Delaware and Raritan Canal (right-of-way listed 5/11/73). The canal is no longer in use for navigation of boats. The bridge is near a high rise residential building and a wooded park area. It is also immediately west of the former Landing Lane thru truss bridge over the Raritan River that was replaced in 1991.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. D&R Canal. 05/11/1973. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The variable depth thru-girder bridge was built as a swing span but it is now stationary. The motor has been removed, and structural supports now block the ring around which the bridge once rotated. Timber blocking supports are present at the abutment. The pipe railing is original. One of several swing spans built by the PA RR when the canal was in decline, its value is for its historical association rather than its technological significance. The bridge was made inoperable about 1969.

DESIGNER/PATENT PA RR OFFICE OF ENGINEER **BUILDER**

SETTING / CONTEXT The bridge crosses the D & R Canal Feeder in a mid-19th century residential section of Trenton dominated by row houses interspersed with warehouses. The area has been redeveloped, so the historic setting of the canal and neighborhood has been lost. Some vacant land adjacent to canal (lined with sheet piling) and bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. D&R Canal. 05/11/1973. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Although the right-of-way of the feeder is listed in the Register, the low rise slab bridge with a concrete parapet that replaced a swing span in 1916 is not. The feeder, which is still part of the regional water system, was closed to traffic about 1913, and fixed bridges were designed and built by the PA RR at all the canal crossings in Trenton ca. 1920. This is one of 11 nearly identical slab bridges over the canal. Parkside Ave. is the more significant of the feeder bridges in Trenton.

CONSTRUCTION DT 1920 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT PA RR OFFICE OF ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane city street and sidewalks over the D&R feeder canal in the center of Lambertville, a NR-listed historic district. Many converted 19th century buildings serve as retail businesses. Adjacent to the bridge is a former Bel-Del RR station. The canal feeder was closed to waterborne traffic about 1913. The canal R-O-W is also NR-listed, but bridges over it are not. The bridge is not a contributing resource to either district because of its age and style.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Lambertville Historic District. 06/30/1983. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The steel stringer bridge with concrete abutments and paneled concrete parapets is similar to others over the feeder canal in Mercer county. The modest bridge was constructed in 1920, after the canal feeder was closed to navigation. Although located within the historic district noted for its transportation network, the bridge is outside of the 19th-century period of historical significance and is thus a noncontributing resource. It is also not technologically noteworthy.

SETTING / CONTEXT The bridge carries a 2-lane street and 2 sidewalks over the Delaware & Raritan Canal Feeder. It is located near a thru truss bridge spanning the Delaware River on one of the two major streets in the town. It is also near the bridge guard's shanty. The canal feeder right-of-way is National Register-listed, but the bridges that cross the canal and feeder are not part of the nomination. The span was built after the canal feeder was closed to navigation about 1913.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. D&R Canal. 05/11/1973. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete tee beam bridge is supported on a concrete center pier and concrete abutments and wingwalls. The four narrow tee beams with diaphragms are widely spaced. The concrete parapet with posts is ornamented with 4 light standards cast by the Foran F & M Co. of Flemington. The bridge is not technologically innovative or significant, and it was constructed after the canal feeder was closed to navigation (about 1913). The bridge was designed by the railroad because they owned the canal.

DESIGNER/PATENT HARRINGTON, HOWARD & ASH **BUILDER** PHOENIX BRIDGE COMPANY

SETTING / CONTEXT The bridge carries two lanes of traffic and a single sidewalk over the Great Egg Harbor north of Ocean City. South of the bridge is a late 20th-century summer residential community bordering the beach. To the north is a salt marsh and causeway. The bridge is the northernmost of five movable span bridges on Cape May County's Ocean Highway. It is privately owned and operated by the Ocean City Coastal Hwy Bridge Co. It is currently posted for 3 tons.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1928 bridge consists of a double leaf bascule span, 5 deck girder spans, and 79 steel stringer approach spans. The bascule has a two story concrete operators house; original open gearing, electric motors, haunched deck girder superstructure, concrete counterweights, and concrete substructure. The bridge is one of the earliest examples of a movable Harrington, Howard & Ash design in NJ. It is historically distinguished, and a very complete example of its type.

INFOR MATION

Bibliography:
Cape May County Bridge Commission. HNTB. "Engineering Report to Cape May County Bridge Commission on Existing Ocean Highway Toll Bridge Cape May County New Jersey," July 1, 1965.
Cape May County Bridge Commission. Minutes 1934-1940. Brown, Kathi Ann. Design By Diversity. Kansas City, Missouri: The Lowell Press, 1989.New Jersey Laws, Session of 1910.

Physical Description: The main span of the 3437'-long bridge is a 122'-long double-leaf trunnion haunched deck-girder span with a steel grid deck. The multi-girder approach spans are supported on concrete pile and cap beam bents, and the whole bridge is enclosed by a 3-rail high metal railing installed in 1947-48. Opposing corners of the movable leafs are set with 2-story, flat-roofed concrete operators houses supported on bracketed cantilevers from the concrete piers. The other corners have one-story machinery houses that also serve as lookouts off the safety walks.

Although there have been some changes to the bridge as a result of maintenance and improvements, overall the structure and operating mechanism are complete. The bridge appears and operates as originally designed with the leafs pivoting on the original trunnions. A counterweight is affixed to the tail end of each leaf. The operating machinery, with open gear sets and shafts, appears to be largely original or in kind replacements. The electrical and control systems also appear to be largely original, but the trolley-like control panel and dead men were replaced with a modern panel and wiring in 1993. The safety gates are modern, and the original signals were removed in 1993. The one-story, hip-roofed structure at the south end of the bridge is the original office for the bridge company. It has a modern overhead garage door on the south elevation and an exterior coating added in 1993, but otherwise it complete and contributes to the historical significance of the span. It is now used as a day room.

The original toll booth was replaced by the present one in 1977. There have been repairs to several approach span bents, and the bridge is currently posted for 3 tons.

Historical and Technological Significance: The double-leaf trunnion bridge was built by the Ocean City Coastal Highway Bridge Company and its subsidiary Ocean City Longport Automobile Bridge Company in 1927-1928. The company was chartered by the state legislature in 1927, and they contracted with Harrington, Howard & Ash (later Ash, Howard, Needles & Tammen) of Kansas City, Missouri and New York for the design. The span is the earliest of the bridges between the barrier islands in Cape May and Atlantic counties, and it is the second of the Ash, Howard, Needles & Tammen-design movable spans that would become extremely popular in the region (the earliest is 0406158, US 30 over Cooper River built in 1927). The bridge is significant as an early and remarkably complete example of its type and design, with most of its original operating machinery, and for its historical significance with the practice of being erected by a private-sector organization (criteria A. C.). Technologically it represents mid-1920s refinements in the important trunnion bascule bridge design developed in Chicago in the last years of the 19th and early years of the 20th century. The Ocean City-Longport bridge is one of over a dozen of the same patented design built in the region between 1928 and 1940. Another of the same design was built on the Ocean Highway over Corsons Inlet for the Cape May Bridge Commission in 1947-48 (not included in the survey because of it date of construction).

The Ocean City-Longport bridge company was not financially successful, and the owners filed for bankruptcy in August, 1934. In 1946, the Cape May County Bridge Commission, which owned and operated 6 other bridges further south on the Ocean Highway, refinanced its indebtedness in order to be able to purchase and rehabilitate the bankrupt Ocean City-Longport bridge. They paid $720,000 for it. The bridge had suffered from deferred maintenance during the 1930s and war years. Starting in 1947, the commission rehabilitated it by reconditioning the deck of the approach spans. The original concrete deck was completely removed, supporting girders and floor beams were realigned and repaired where needed, it was redecked with concrete, and new metal railings were installed. The roadway and sidewalk were reconfigured with two safety walks flanking the 23'-wide cartway instead of the original arrangement of one 5'-wide sidewalk. Repairs were also made to the electrical equipment and the operators houses. New doors and windows were installed on the operators houses in 1955, and the steel grid deck was also installed on the movable leafs then.

The Cape May County Bridge Commission, owners of the bridge since 1946, was established by the county in 1934 for the purpose of having a means to apply for Federal Emergency Administration of Public Works funds to build movable bridges over navigable channels and two fixed bridges on the Ocean Highway in the county. A quasi-public commission, the original members were George N. Smith from Wildwood Crest, Luther C. Ogden, a former county freeholder, of Cape May City, and G. W. Bergner, mayor of Avalon. The purpose of the commission was to "finance, construct, maintain, and operate self-liquidating toll bridges within the county." Having the private commission meant that the bridges could be constructed without cost to the county. Improving vehicular access to the Shore resort communities was viewed as a means of balancing the decline of train service to the tourist and seasonal-resident oriented area.

Ocean Highway was a route designation enacted by the 1910 New Jersey Senate and General Assembly (Chapter 220). The highway was to stretch from Atlantic Highlands in Monmouth County to Cape May City in Cape May County along, "as far as possible," improved existing roads near the ocean. The Commissioner of Public Roads was authorized to make route improvements where necessary with a $50,000. appropriation from the vehicle license fund. The improvements were made to the roadway over the next four years, but bridges were not a part of that work.

Ocean Highway was an element in the promotion of the Jersey Shore as a tourist and seasonal residence area. The route, which incorporates local and county streets, does not possess the integrity of setting nor technological significance to be evaluated as a potential historic district. It is merely a route designation that in Cape May County was promoted as the shortest route from Atlantic City to Cape May City.

The consulting engineer firm of Harrington, Ash & Howard (reorganized in 1928 as Ash, Howard, Needles & Tammen) from New York City played a pivotal role in the history of private bridge commissions in the region. By 1928, the firm, founded in Kansas City, Missouri in 1914 as the successor to one started by J.A.L. Waddell, had established itself nationally as one of the leading designers of movable bridges, especially vertical lift bridges. Waddell was associated with the firm until he and John Harrington went their separate ways in 1914. The company opened its New City office in 1922 under the leadership of John L. Harrington who had taken on new partners. The patent associated with the design of this particular bridge relates to the trunnion tower, and it was granted in 1926.

Boundary Description and Justification: The bridge is evaluated as individually significant because of its technology, its completeness, and its historic background. It is not located within a potential historic district nor along a potentially eligible historic route. Therefore, the significant boundary is limited to the substructure and superstructure of the entire span.

SETTING / CONTEXT The toll bridge carries two lanes of traffic and two sidewalks over a navigable channel between Sea Isle City and Avalon. North of the bridge is Townsend's Inlet municipal park with beach and parking lot. The area on both sides of the inlet is developed with late-20th century summer residences. The toll bridge is privately operated by the Cape May County Bridge Commission.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 27 span bridge has a single-leaf bascule span and 26 deck girder and rolled stringer approach spans. The 57' tapered deck girder with floor beams trunnion bascule is well preserved with its original or inkind replacement gear sets, electrical systems, controls, and concrete operator's and mechanical houses. The bridge is 1 of 4 similar bridges built 1938-1940 for the Cape May County Bridge Comm. with funding from the WPA. All are historically and technologically significant.

INFOR MATION

Bibliography:
Brown, Kathi Ann. Design By Diversity. Kansas City, Missouri: The Lowell Press, 1989.
Cape May County Bridge Commission. Minutes 1934-1940.
New Jersey Laws, Session of 1910.
Seely, Bruce. Building the American Highway System. Philadelphia: Temple University Press, 1989.

Physical Description: The main span of the 27-span bridge is a 57'-long haunched deck girder with floor beams single-leaf trunnion bascule with a steel grid deck. The concrete counterweight is affixed to the underside of the tail end of the movable span. The approach spans are stringers and built-up deck girders supported on concrete pier bents with concrete cap beams for the stringers and braced concrete columns for the girders and movable leaf. A metal railing and safety sidewalks flank the roadway of the entire span. The cantilevered flat-roofed concrete Moderne-style operator's house on the inland side of the movable leaf is matched by a corresponding lookout with a bench on the ocean side. The toll booth is also a flat-roofed concrete structure, and it is located in the center of bridge adjacent to the movable leaf. The toll taker also serves as the bridge operator. Safety gates and signals are activated from the toll booth, but all other controls for operating the span are in the nearby operator's house.

The operating mechanisms are primarily original or in kind replacements. The bridge operates by means of a pinion that engages a rack fixed to the outside of the girder near the trunnion. The enclosed primary and open secondary reducers and open drive gear sets are original as are the trunnions and supporting columns. The control panel and electrical panel also appear to be original. The bridge is powered by an electrical motor.

Historical and Technological Significance: The bridge over Townsends Inlet is one of four nearly identical trunnion movable bridges designed by Ash Howard Needles & Tammen that were built under one contract for the Cape May County Bridge Commission in 1938-1940. The bridges were opened to the traveling public June 1940. The span is a well preserved representative example of what is the most common movable bridge type in the Jersey Shore region. Technologically it represents mid-1920s refinements in the important trunnion bascule bridge design developed in the early years of the 20th century. It is one of over a dozen of the same patented design built in the area between 1928 and 1940. Another was built on the Ocean Highway over Corsons Inlet for the Cape May Bridge Commission in 1947-48. Historically the bridges are monuments to the effectiveness of Depression-era New Deal programs to improve America's infrastructure (criteria A. C.).

The Cape May County Bridge Commission was established by the county in 1934 for the purpose of having a means to apply for Federal Emergency Administration of Public Works funds to build movable bridges over navigable channels and two fixed bridges on the Ocean Highway in the county. A quasi-public commission, the original members were George N. Smith from Wildwood Crest, Luther C. Ogden, a former county Freeholder, of Cape May City, and G. W. Bergner, mayor of Avalon. The consulting engineer firm of Ash Howard Needles & Tammen (AHNT) from New York City played a pivotal role in the history of the bridge commission. By 1934, the firm, founded in Kansas City, Missouri in 1914 as the successor to one started by J.A.L. Waddell, had established itself nationally as one of the leading designers of movable bridges, especially vertical lift bridges. Waddell was associated with the firm until he and John Harrington went their separate ways in 1914. The company opened its New City office in 1922 under the leadership of Harrington, Howard and Ash. Work-relief program funded projects were an important source of work for AHNT, as it was for most engineering firms during the Depression, and the Cape May Ocean Highway bridges were a sustaining project for the New York office. The AHNT patent associated with the design of this particular bridge relates to the trunnion tower, and it was granted in 1926.

It was reported at the May 22, 1935 annual meeting of the Cape May County Bridge Commission that AHNT attended the meeting, and that they had prepared, on behalf of the commission, the actual application, complete with plans and specifications, to the Federal Administration of Public Works for $1,650,000 to build the Ocean Highway bridges. The application was not approved until June 14, 1938, at which time $744,545 was a grant and $910,000 was a loan. Work on the bridges began immediately.

The funding from the Federal Administration of Public Works met several objectives of various federal programs. It provided work for the unemployed. It was anticipated that between 350 and 500 local men would be put to work in addition to many "outside men," (CMCBC Minutes, 7/1/38). The bridges would improve traffic and focus on efficiency, as defined in engineering terms, which was a goal of the Bureau of Public Roads. Work relief-funded projects like the Cape May County Ocean Highway bridges kept the golden age of highway development alive during the Depression, when the lack of state and local funds would otherwise have stopped the effort (Seely, p. 88-91).

The four AHNT-designed movable bridges built on the Ocean Highway (3100003, 0500028, 3100005, 3100006) are all evaluated as significant because all are in a nearly complete state of preservation. The fact that they were built with funds made available through the federal government in an effort to create work is not sufficiently significant enough to meet National Register criteria because so many public works projects during the mid- to late-1930s were funded exactly the same way. The bridges were also not built with federally funded work crews such as the Civilian Conservation Corps (CCC).

Boundary Description and Justification: The bridge is evaluated as individually distinguished. While its immediate setting remains unchanged, the route of which it is a part does not possess the integrity or historical significance to be a potential historic district. Therefore, the bridge including the approach spans and structures related to its operation are evaluated as the limit of the historic resource.

Physical Description: The main span of the 22-span bridge is a 57'-long haunched deck girder with floor beams single-leaf trunnion bascule with a steel grid deck. The concrete counterweight is affixed to the underside of the tail end of the movable span. The approach spans are stringers and built-up deck girders supported on concrete pier bents with concrete cap beams for the stringers and braced concrete columns for the girders and movable leaf. A metal railing and safety sidewalks flank the roadway of the entire span. The cantilevered flat-roofed concrete Moderne-style operator's house on the inland side of the movable leaf is matched by a corresponding lookout with a bench on the ocean side. The toll booth is also a flat-roofed concrete structure, and it is located in the center of bridge adjacent to the movable leaf. The toll taker also serves as the bridge operator. Safety gates and signals are activated from the toll booth, but all other controls for operating the span are in the nearby operator's house.

The operating mechanisms are primarily original or in kind replacements. The bridge operates by means of a pinion that engages a rack fixed to the outside of the girder near the trunnion. The enclosed primary and open secondary reducers and open drive gear sets are original as are the trunnions and supporting columns. The control panel and electrical panel also appear to be original. The bridge is powered by an electrical motor.

Historical and Technological Significance: The bridge over Middle Thorofare is one of four nearly identical trunnion movable bridges designed by Ash Howard Needles & Tammen that were built under one contract for the Cape May County Bridge Commission in 1938-1940 (3100003, 0500028, 3100005, 3100006). The bridges were opened to the traveling public June 1940. The span is a well preserved representative example of what is the most common movable bridge type in the Jersey Shore region. Technologically it represents mid-1920s refinements in the important trunnion bascule bridge design developed in the early years of the 20th century. It is one of over a dozen of the same patented design built in the area between 1928 and 1940. Another was built on the Ocean Highway over Corsons Inlet for the Cape May Bridge Commission in 1947-48. Historically the bridges are monuments to the effectiveness of Depression-era New Deal programs to improve America's infrastructure (criteria A. C.).

The Cape May County Bridge Commission was established by the county in 1934 for the purpose of having a means to apply for Federal Emergency Administration of Public Works funds to build movable bridges over navigable channels and two fixed bridges on the Ocean Highway in the county. A quasi-public commission, the original members were George N. Smith from Wildwood Crest, Luther C. Ogden, a former county Freeholder, of Cape May City, and G. W. Bergner, mayor of Avalon. The purpose of the commission was to "finance, construct, maintain, and operate self-liquidating toll bridges within the county." Having the private commission meant that the bridges could be constructed without cost to the county. Improving vehicular access to the Shore resort communities was viewed as a means of balancing the decline of train service to the tourist and seasonal-resident oriented area.

Ocean Highway was a route designation enacted by the 1910 New Jersey Senate and General Assembly (Chapter 220). The highway was to stretch from Atlantic Highlands in Monmouth County to Cape May City in Cape May County along, "as far as possible," improved existing roads near the ocean. The Commissioner of Public Roads was authorized to make route improvements where necessary with a $50,000. appropriation from the vehicle license fund. The improvements were made to the roadway over the next four years, but bridges were not a part of that work.

Ocean Highway was an element in the promotion of the Jersey Shore as a tourist and seasonal residence area. The route, which incorporates local and county streets, does not possess the integrity of setting nor technological significance to be evaluated as a potential historic district. It is merely a route designation that in Cape May County was promoted as the shortest route from Atlantic City to Cape May City.

The consulting engineer firm of Ash Howard Needles & Tammen (AHNT) from New York City played a pivotal role in the history of the bridge commission. By 1934, the firm, founded in Kansas City, Missouri in 1914 as the successor to one started by J.A.L. Waddell, had established itself nationally as one of the leading designers of movable bridges, especially vertical lift bridges. Waddell was associated with the firm until he and John Harrington went their separate ways in 1914. The company opened its New City office in 1922 under the leadership of Harrington, Howard, and Ash. Work-relief program funded projects were an important source of work for AHNT, as it was for most engineering firms during the Depression, and the Cape May Ocean Highway bridges were a sustaining project for the New York office. The AHNT patent associated with the design of this particular bridge relates to the trunnion tower, and it was granted in 1926.

It was reported at the May 22, 1935 annual meeting of the Cape May County Bridge Commission that AHNT attended the meeting, and that they had prepared, on behalf of the commission, the actual application, complete with plans and specifications, to the Federal Administration of Public Works for $1,650,000 to build the Ocean Highway bridges. The application was not approved until June 14, 1938, at which time $744,545 was a grant and $910,000 was a loan. Work on the bridges began immediately.

The funding from the Federal Administration of Public Works met several objectives of various federal programs. It provided work for the unemployed. It was anticipated that between 350 and 500 local men would be put to work in addition to many "outside men," (CMCBC Minutes, 7/1/38). The bridges would improve traffic and focus on efficiency, as defined in engineering terms, which was a goal of the Bureau of Public Roads. Work relief-funded projects like the Cape May County Ocean Highway bridges kept the golden age of highway development alive during the Depression, when the lack of state and local funds would otherwise have stopped the effort (Seely, p. 88-91).

The four AHNT-designed movable bridges built on the Ocean Highway (3100003, 0500028, 3100005, 3100006) are all evaluated as significant because all are in a nearly complete state of preservation. The fact that they were built with funds made available through the federal government in an effort to create work is not sufficiently significant enough to meet National Register criteria because so many public works projects during the mid- to late-1930s were funded exactly the same way. The bridges were also not built with federally funded work crews such as the Civilian Conservation Corps (CCC).

Boundary Description and Justification: The bridge is evaluated as individually distinguished. While its immediate setting remains unchanged, the route of which it is a part does not possess the integrity or historical significance to be a potential historic district. Therefore, the bridge including the approach spans and structures related to its operation are evaluated as the limit of the historic resource.

SETTING / CONTEXT The bridge is an approach to the east side of the US 22 bridge over the Delaware River. The eastern approach spans carry four lanes of the highway and two sidewalks over a two-lane street, a one-track railroad and property owned by the Delaware River Joint Bridge Toll Commission.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The five-span deck girder bridge with concrete piers and an abutment is skewed to carry a curved roadway. The abutment, pier columns and the arched struts are scored. The simple-span girders are built-up and support rolled floorbeams which support stringers and the deck. Overhang brackets support the sidewalk with a metal railing at each face. The bridge is structurally part of the truss bridge owned and operated by the Delaware River commission. The bridge's main span, which carries US 22 over the Delaware River is potentially eligible to listed under Criteria C, but, was outside the scope of the survey. This approach spans would have the same NR status as the main truss spans.

SETTING / CONTEXT The single-lane bridge spans the spillway from Mill Pond within the Double Trouble Historic District, an early-20th century cranberry bog village. The district is located within Double Trouble State Park. The bridge is structurally associated with a dam and raceway once used to store water for the bogs and to supply water power for a saw mill. The dam, but not the bridge, is listed as a contributing structure in the National Register nomination.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Listed. Double Trouble Historic District. 02/23/1978. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span concrete arch bridge with stepped wingwalls is an integral feature of the Double Trouble Historic District's Mill Pond Dam. The bridge has been gunited, wood railings added, and the six-bay timber gate frame rebuilt. The bridge was probably built c.1909 when the Double Trouble Company purchased the land and expanded the cranberry bogs. The bridge is a representative example of period technology, and makes a significant contribution to the National Register district.

INFOR MATION

SOURCES:
Double Trouble Historic District Nomination. New Jersey State Historic Preservation Office. 1977.

PHYSICAL DESCRIPTION: The two-span reinforced-concrete barrel arch bridge crosses the spillway from Mill Pond dam. The bridge has stepped concrete wing walls and pier. Extending between the upstream abutments is a 6-bay timber frame for the spillway gates. The frame has been rebuilt but the metal gate racks and gears appear older. The earth-filled arch bridge has a gravel road surface and wood railing. The bridge has been sprayed with gunite.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Cows Head Road over Cedar Creek bridge is within the boundaries of the Double Trouble Historic District, an early-20th century cranberry bog and village. The bridge is a contributing structure to the historic district and is eligible under National Register Criterion A. The bridge is upstream from the village and is part of the dam and water system used to maintain the cranberry bogs. Stylistically the bridge dates from the first decades of the 20th century, and probably was constructed c.1909 when the Double Trouble Company improved the cranberry bogs.

The Double Trouble National Register Nomination rates the Mill Pond dam, of which the bridge is structurally a part, as a contributing structure. However, the bridge is not specifically rated in the National Register Nomination. Considering the bridge is a representative example of period technology and an integral part of the district's water and irrigation systems, it thus makes a significant contribution to the National Register District.

The bridge has been altered by the reconstruction of the spillway gate frame, the addition of modern wood railings, and the application of gunite. The alterations do not compromise the bridge's contribution to the historic district.

BOUNDARY DESCRIPTION AND JUSTIFICATION: The bridge is within the described boundaries of the Double Trouble Historic District as delineated on the Toms River USGS quad map accompanying the nomination.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The one-lane bridge carries an unimproved road over the Tulpehocken Creek in the Wharton State Forest, which the state purchased in the 1950s and 1960s from the estate of Joseph Wharton, a Philadelphia financier who had originally planned to secure a water supply for Philadelphia. Currently, the forest is primarily recreational, and the stream that flows under the bridge is a canoe route.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span timber stringer bridge rests on timber piles and abutments. The piles are square, and the pile bents have horizontal and diagonal traverse bracing. The timber railing is braced from extensions of the timber pile caps. The bridge has timber curbs. The bridge is in good repair, suggesting that much of the fabric has been replaced inkind since erection in 1940. The bridge is technologically and historically undistinguished. It was transferred to state jurisdiction in 1955.

DESIGNER/PATENT PORT AUTHORITY OF NEW YORK **BUILDER**

SETTING / CONTEXT The 8-lane bridge carries I-95, median, and 2 safety sidewalks over the 4-lane Hudson Terrace. The bridge was built in 1930 as part of the George Washington Bridge (GWB) project, and was designed to carry the upper level approach traffic over an important 1920s N-S route. The GWB approach, itself, does not constitute a historic corridor because it is not technologically innovative and has lost its integrity of setting with numerous modern intrusions including high-rise buildings.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Rt 46 Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 2/21/97.

SUMMARY The 4-span encased steel stringer bridge rests on stone abutments and steel rigid-frame bents. In 1964 it was widened on both sides with rolled steel stringers. Original metal railings remain and Port Authority maintenance buildings have been constructed under the two end spans. The bridge is structurally and visually associated with the adjacent nationally distinguished GWB. It is the only NJ approach span constructed by the Port Authority and is historically significant.

INFOR MATION

Bibliography:
AGLAS. "Port Authority of NY and NJ, Inspection Report," 1990.
Transactions of the American Society of Civil Engineers, vol. 97, 1933.
Paper No. 1825, "George Washington Bridge: Approaches and Highway Connections" by J.C. Evans, Esq.
"Plan of New Jersey Approach," Engineering News-Record. Vol. 107 (Oct. 22, 1931), pp.662-664.
Bauer, J.L. "New Jersey Approaches to the George Washington Bridge." Civil Engineering. Vol. 2, No. 3 (March, 1932), pp. 160-163.

Physical Description: The 4-span, 94'-wide stringer bridge with encased and exposed rolled I-section steel stringers is supported on reinforced concrete abutments and built-up steel rigid frame bents. The encased stringers are those in the original, center portion of the 174'-long span. A modern concrete median barrier separates opposing traffic, and a 2' wide safety walk is at each fascia. The bridge is finished with a modern, 3- rail high metal railing of standard state design. Originally built in 1930, the span was widened on both sides in 1964 with rolled steel stringers. Port Authority storage facilities were constructed under the end spans adjacent to the abutments.

When the lower level of the George Washington Bridge was opened in the early 1960s, traffic to and from that level is carried via ramps that pass under Hudson Terrace.

Historical and Technological Significance: While the encased stringer bridge was constructed as part of the New Jersey approach network to the National Register-eligible George Washington Bridge, neither it does not have integrity of original design and setting. It was widened on both sides in 1964, and the original railing was also replaced with the present one at that time. In addition to the structural alterations, the setting has been significantly changed to accommodate access to the lower level of the George Washington Bridge that was opened in the early 1960s. While the suspension bridge is significant, this bridge is too altered to be significant. The rigid frame bents are found on other bridges in the region that possess integrity of setting and design (0917150).

"It was deemed desirable in planning the New Jersey approach to accomplish the actual traffic distribution at as great a distance from the bridge as economical and physical considerations would permit, and at the same time avoid all semblance of a plaza where undue concentration of traffic could occur" (EN-R). Three state highways (NJ 1,4,6) and local roads are distributed into or from the approach road west of Linwood Avenue in Ft. Lee. From that point east to the toll plaza, local streets are carried over the approach road on overpasses. After the toll plaza, the approach road is carried over the easternmost local street, Hudson Terrace. The goal of the planners and designers was to eliminate all grade crossings and safely speed up traffic. It was accomplished, like it had been on other projects undertaken by the New Jersey State Highway Department, by overpasses and ramped breakouts. With the exception of the 3-level grade separation near the western limits of the approach, which presents "the most interesting structural layout of the project" (0202160, 0206187; evaluated as eligible) (EN-R), the design of the highway, interchanges, and structures is not innovative and is representative of ideas and designs that the Department had used elsewhere throughout state.

Interestingly, the decision was made in 1929 to build the approach roads and structures to their full capacity and width, although only half the anticipated demand existed when the GW bridge was completed. It was expected that the facility would never have to be widened. Since completion in 1930, there have been many changes to the distributing highways and their ramps. When the lower level of the bridge was planned in 1959, the viaduct over Hudson Terrace was to be widened, and the ramp servicing the Palisades Parkway was added. At that time the bridge lost its integrity of original design. While the historical significance of the bridge is unchanged (it is still the closest approach span to the west end of the GW bridge, and it was built as part of that large project), it does not appear as it did when it achieved its historical significance and is thus not an eligible resource.

The Port of New York Authority designed the approach as far west as Lemoine Avenue, but they built (secured the property and paid for) the portion only as far as Hoyt Street, which is about the location of the toll plaza. The Authority paid the state of New Jersey to build the rest of the approach road and to improve the state routes feeding the approach (EN-R). The Port Authority design team was headed by J.C. Evans, terminal engineer. New Jersey's efforts were lead by J.L. Bauer, New Jersey State Highway Engineer, and Morris Goodkind, state bridge engineer. The New Jersey work was built by M. Brewster & Sons of Bogota, NJ.

DESIGNER/PATENT PORT OF NEW YORK AUTHORITY **BUILDER**

SETTING / CONTEXT The bridge carries NJ 495, the divided six-lane approach highway to the Lincoln Tunnel, over a busy urban street. It is located in an urban area of 1920s houses with some post-1950 infill, plus some commercial and residential buildings from other eras nearby. The bridge is part of the limited access corridor that links US 1&9 with the 1937 Lincoln Tunnel through congested Hudson County.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The bridge is composed of four well detailed haunched deck girders with built-up floor beams and is supported on bearings on concrete columns. Outer portions of the substructure, which includes columns faced with a Moderne-style stone veneer, is similar to the detailing on other bridges along the 1937-38 approach to the Lincoln Tunnel. The bridge is not individually distinguished, but it is significant as part of an important limited-access highway that is technologically noteworthy.

INFORMATION

Bibliography:
Ammann, O.H. (Chief Engineer of the PA): "Planning the Lincoln Tunnel Under the Hudson" in Civil Engineering, 7, June 1937, 387-391).
Condit, Carl: American Building Art, Twentieth Century (NY: Oxford Univ. Press, 1961).
Port Authority: Annual Reports, 1956

Physical Description: The single-span haunched deck girder bridge composed of four girders with rolled floor beams is supported on engaged columns set into stone-faced concrete abutments. The stringer and floor beam connections are riveted. The girders are nicely detailed, and the roadway is enclosed by a metal fence-like railing. The bridge carries the elevated limited access highway over a city street, and it is linked to other sections of the highway by T-beam viaducts. The bridge is well preserved.

Historical and Technological Significance: The girder bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

SETTING / CONTEXT The structure carries an elevated portion of NJ 495, a divided 6-lane highway serving as the approach to Lincoln Tunnel, over vacant land between two city streets. It connects 3800019, a deck girder span over a city street, with 3800024 over Park Avenue. The surrounding residential area is mainly early-20th century row houses with post-1950 houses and apartment buildings added as infill.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.
CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The 172'-long viaduct composed of T-beam spans on concrete piers is finished with arched fascia beams. A concrete parapet encloses the roadway, and a stone-faced parapet serves as a curb on the lower level. The bridge is a well-preserved original element of the 1937-38 corridor to link US 1&9 with the newly opened first tube of the Lincoln Tunnel. The highway is a historically significant and technologically innovative solution to building a superhighway through a congested area.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, (June, 1937), pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The approximately 13-span T-beam and slab structure is finished with arched fascia beams, concrete columns, and concrete parapets. The viaduct is part of a large, continuous structure, so the exact number of spans was not determined. The slab is used where the viaduct, used to maintain grade between two deck girder bridges over local streets, is founded on bedrock. The bridge is detailed to match other spans on the 2.8-mile long limited access route. It appears to be unaltered.

Historical and Technological Significance: The T-beam and slab viaduct is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.
CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The bridge, part of a 5-component interconnected structure, is composed of a simply supported built-up deck girder with floor beams on the inside (north), and a much shallower outside girder that is carried on varying length rolled I-section columns that bear on the girder of 380023. In turn, the north side girder for the bridge also supports Bridge 3800024 via the same I-section posts. The well-preserved bridge is part of a historically and technologically significant thoroughfare.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, (June, 1937), pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The deck girder bridge is part of a 5-component, interconnected span. This section is composed of a simply supported built-up deck girder with floor beams on the inside (north) and a much shallower outside girder that is supported on a series of varying height rolled I-section columns that bear of the girder for 3800023. In turn, the north girder of this bridge serves as the bearing for columns that support 3800024. The roadway is enclosed by a metal railing that matches that used all along the roadway. The structure appears unaltered.

Historical and Technological Significance: The deck girder bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

SETTING / CONTEXT The bridge carries an elevated portion of the divided 6-lane highway approach to Lincoln Tunnel, over a busy city street. It is part of a 4-structure overpass that also carries an access ramp to US 495 and a local-traffic service road over Park Ave. The 3-level structure is located in a predominantly early-20th century residential area of row houses. This bridge is flanked by spans 0917163 (north) and 0917162 (south).

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.
CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The bridge is composed of interior built-up girders that bear on engaged columns and rolled stringers with stiffeners on the outside. All are connected by floor beams, and the rolled stringers bear on steel columns carried by the flanking girders of parallel spans. A plain metal railing is used as a protective barrier. The well-preserved bridge is an original element in the technologically innovative and historically significant roadway developed through a congested area in the late 1930s.

SETTING / CONTEXT The viaduct carries NJ 495, the divided 6-lane highway approach to the Lincoln Tunnel, between JFK Blvd. East (3800027) and Park Ave. (3800024). It is an element in a limited-access highway that passes through a residential area dominated by 1920s and post-1950s detached townhouses and apartment buildings. Weehawken Town Hall is to the south on the east side of the Palisades.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The T-beam structure maintains the elevation of NJ 495 between other bridges over city streets. It is finished with arched fascia beams to repeat the detailing of similar spans on the route. The center of the viaduct is carried on bedrock. While not individually significant, it is a contributing element to the historically and technologically significant 1937 road that linked a major Hudson River crossing with the west side of the Palisades.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, (June, 1937), pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The 6-span T-beam viaduct is finished with arched fascia beams, concrete columns, every other one of which is load-bearing, and concrete parapets. The viaduct is part of a large, continuous structure that carries the limited access highway above the grade of the parallel city street. The viaduct is also used to maintain grade between two deck girder bridges over local streets, is founded on bedrock. The bridge is detailed to match other spans on the 2.8-mile long limited access route. It appears to be unaltered.

Historical and Technological Significance: The T-beam viaduct is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). SETTING / CONTEXT The bridge carries NJ 495, the divided six-lane approach highway to the Lincoln Tunnel, over a busy city street and service road in Weehawken. It is located in an urban residential area of 1920s through post-1950 detached town houses and apartment buildings.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.
CONSULT DOCUMENTS SHPO Comments 11/17/99, Letter 03/12/01.

SUMMARY The multi-span curved bridge is composed of varying length built-up deck plate girders supported on concrete columns and abutments, some with stone facing that matches the masonry used along the historic approach to the 1937 Lincoln Tunnel. Most girders are haunched. The roadway is enclosed by a metal railing. The bridge is an impressive and technologically significant application of deck plate girder technology to a complex engineering problem. It is individually eligible for listing in the National Register of Historic Places and would be a contributing element of the potential 495/ Lincoln Tunnel Approach Historic District under Criteria A and C.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The 5-span built-up deck girder bridge is part of the continuous elevated structure that serves as the approach to the Helix. It is the uphill or western end of the Helix. The flared multi girder bridge is made up of haunched girders with an aesthetic geometric arrangement of the stiffeners on the outer face and plain built-up girders on the interior. The floor beams are also built up. The girders vary in length, owing to the flared shape of the span, and are supported on concrete columns, some of which are stone faced. The bridge appears to be unaltered.

Historical and Technological Significance: The deck girder bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). SETTING / CONTEXT The bridge carries an exit ramp from NJ 495, the divided six-lane highway approach to the Lincoln Tunnel, over the north service road for NJ 495. It is contiguous to 3800027, and it branches off the north side of that structure. The ramp is located in a densely developed residential area of largely of 1920s detached houses with infill post-1950 houses.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The skewed 2-span haunched built-up deck girder bridge with built-up floor beams of varying lengths is supported on concrete columns. It is a ramp leading from an elevated span of similar construction to a surface road. The concrete columns are faced in the same Moderne-style masonry as other spans on the historic 1938 approach to the Lincoln Tunnel. The span is not technologically significant, but it is a contributing element on a historically and technologically noteworthy route.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port of New York Authority. Annual Report. 1956.

Physical Description: The 2-span built-up deck plate girder bridge is part of the continuous elevated structure that serves as the approach to the Helix. It is the uphill or western end of the Helix, and it is best described as the north elevation of 3800027, the structure almost parallel to it on the south. The flared bridge is made up of haunched girders with an aesthetic geometric arrangement of the stiffeners on the outer face and plain built-up girders on the interior. The floor beams are also built up. The girders vary in length, owing to the flared shape of the span, and are supported on concrete columns, some of which are stone faced. The bridge appears to be unaltered.

Historical and Technological Significance: The deck girder bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. DESIGNER/PATENT PORT OF NEW YORK AUTHORITY **BUILDER**

SETTING / CONTEXT The bridge is part of a long structure that carries NJ 495, the divided 6-lane approach to the Lincoln Tunnel, over a busy avenue. It is part of the "helix" and serves as the bottom section of that viaduct, carrying the road up from the tunnel to Bergen Hill. It is located next to the tunnel's toll plaza. It is part of the structure that includes 3800031 and concrete girder approach spans.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Comments 11/17/99, Letter 03/12/01.

SUMMARY The 2-span bridge was originally composed of a series of 3 built-up haunched deck girders supported on stone-faced concrete columns. It was widened by enlarging the abutments/pier in the same style and adding an additional built up girder. Care was taken to match original detailing. The bridge is eligible as part of the engineering technology which functioned to collect traffic and funnel it into the Lincoln Tunnel. An especially notable feature is the helix which carries the highway from the plaza level up to the cut through Bergen Hill. The structure is individually eligible for listing in the National Register of Historic Places and would be a contributing element of the potential 495/ Lincoln Tunnel Approach Historic District under Criteria A and C.

Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The structure is essentially the foot section or west/uphill end of the Helix viaduct that carries NJ 495 up from the Lincoln Tunnel plaza to the cut through Bergen Hill (3800031). This structure consists of two spans, each with four or five deck plate girders. The outer girders are haunched. The pier and abutments are of reinforced concrete partially faced with stone, with some geometric ornament in the areas not faced. These, plus the geometric decorative railings, and the pattern of the web stiffeners are consistent with the Moderne style found on almost all the original structures on the approach.

In connection with the addition of the third tube, the Port Authority added an additional westbound lane to the loop viaduct on the outside in 1956-57 (Port Authority, 1956, 22-23).. On this portion of the viaduct, great care was taken to preserve the original aesthetic appearance of the bridge. The piers and abutments were extended, using the same stone facing, - and the original outside deck girders, with their curved bottom webs, were moved outward. A new, plain girder was installed where the .original girder had been. Thus the original appearance of the bridge was maintained. In other respects the bridge has not been altered.

Historical and Technological Significance: The multi girder bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of

SETTING / CONTEXT The bridge is part of the helix that brings NJ 495, the six-lane highway approach to the Lincoln Tunnel, from the high level at which it crosses Bergen Hill down close to the level of the tunnel plaza. In so doing it crosses Baldwin Ave. and a rail line. Beneath the bridge is a large NJT bus parking lot, with new mixed use development to the southeast. The Lincoln Tunnel toll plaza is to the west.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Comments 11/17/99, Letter 06/30/95.

SUMMARY The curved viaduct known as the helix is composed of a series of technologically significant concrete girders and 4 longer spans made up of deep Warren deck trusses on the outside matched with haunched deck girders on the inside. All are supported on concrete columns. The viaduct was widened in 1957. It is significant as a complex engineering structure carrying NJ 3, now NJ 495, or the Lincoln Tunnel approach road, up Bergen Hill. The road and tunnel were built by the Port of New York Authority.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: Four of 19 spans of the impressive, 1278'-long, helix-shaped bridge are composed of Warren deck trusses on the outer side and haunched deck girders on the shorter, inner side. The arrangement addresses the difference in length of the two sides of the spans which are located in the most curved portion of the helix-shaped bridge. These rest on concrete columns. The six approach spans at the lower end and nine at the higher end of the viaduct are concrete girders on concrete columns. The upper end of the viaduct bears on a rock abutment. Only a few aesthetic touches have been applied to the structure: the deck girders are detailed with a geometric pattern to the stiffeners and a secondary angle on the outside of the lower web. The columns are scored. In connection with the addition of the third tube, the Port Authority of New York, who has jurisdiction for the span, added an additional westbound lane on the outside face in 1956-57 (Port Authority, 1956, 22-23). New steel pipe columns support the new lane. The bridge spans from the portal of portal of the Lincoln Tunnel to the crest of Bergen Hill where it connects with 3800030.

Historical and Technological Significance: The long, curving viaduct known as the Helix is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The Helix is individually distinguished for its technological significance, and it is also a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

SETTING / CONTEXT The bridge is part of the western approach to the Goethals Bridge over the Newark Bay. The bridge carries westbound traffic off the bridge over the New Jersey Turnpike and Conrail tracks of the Sound Shore Branch. This line follows the Arthur Kill for less than three miles in Union County. It is a branch of the former New York and Long Branch Railroad.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 14-span approach viaduct to the Goethals Bridge is supported on a concrete substructure of columns with arched struts. The original deck girder bridge was widened ca. 1969 and is now supported on larger deck girders to the outside of the original beams. New floorbeams carry the load to the new girder where piers supported the old beams. A single-span thru-girder carries traffic over the train tracks. The structure has not retained its design integrity, and is not historically distinguished.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge carries two lanes of traffic over the Great Egg Harbor River. The bridge, over 4800' in length, spans the river between Beesleys Point in Cape May County, and Somers Point in Atlantic County. The Cape May County side has several heavily altered 19th-century buildings converted to restaurants and a late-20th century electric power plant. The bridge is privately owned and operated by the Beesleys Point Bridge Company.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 120-span bridge has an 80' double-leaf bascule span and 119 steel stringer spans resting on steel jacketed piers with I-beam caps and cross bracing. The substructure has been heavily rebuilt and the steel stringers gunited. The bascule span has modern controls and new electrical systems. Because access to the mechanical rooms was denied, it was not possible to completely assess the span. However, topside inspection shows that the bascule appears heavily altered and is probably not eligible.

DESIGNER/PATENT RALPH MODJESKI **BUILDER**

SETTING / CONTEXT Built in 1926 as the first bridge across the Delaware River at Philadelphia, the handsome suspension bridge connects downtown Camden with Center City Philadelphia. Neither approach is via modern, limited access highways. The bridge links the centers of both cities.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS DOE 03/29/83

SUMMARY When completed in 1926 the Camden-Philadelphia Bridge, as it was originally known, ranked as the longest suspension bridge in the world. The handsome structure, designed by Ralph Modjeski and architect Paul Certe, was the single most influential structure in the subsequent development of Camden and the surrounding area. The span remains as one of the finest and best preserved important suspension bridges in the country and is one of Modjeski's most significant works.

SETTING / CONTEXT The bridge carries one lane of a lightly traveled road over a minor stream on the southern edge of the 19th-century village of Linvale. The village does not have historic district potential due to the alterations to most of the buildings. The bridge is about 100' south of NJ 31 which now serves as the main road through the village. Woodville Road has been bypassed by NJ 31.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stone arch with rubble-coursed spandrel walls and gauged ringstones was widened on the downstream side with a corresponding concrete arch addition at an unknown date. Although the earliest documented stone arch bridge in the county, the span has been altered by the addition, and the stone parapets on both sides have been rebuilt. More complete examples of 19th-century masonry arches survive like 1000111.

SETTING / CONTEXT The bridge is located in an area of late-20th century commercial development. It carries the two-track right-of-way of the Delaware Lackawanna & Western Railroad's New Jersey Cutoff over a two-lane road. The structure is located very close to the Delaware River Viaduct of the same rail line. The development of this r-o-w was a major engineering accomplishment of its day. It is a significant engineering achievement constructed with major cuts and fills, which avoided creating any highway railroad grade crossings along its 28.45 mile length.

CONSULT STATUS Not Individually Eligible. Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Opinion 3/22/94, Letter 03/12/01.

SUMMARY The skewed reinforced concrete arch is flanked by sloping concrete wingwalls. No railings are present at the faces of the bridge, which has a ballasted deck. The structure, which resembles a tunnel, supports very little fill in comparison to other structures on the route. The DL&W's New Jersey Cut-Off is a technologically significant engineering achievement noted for its use of reinforced concrete for bridges and structures and for completely grade separating the railroad and highway crossings. The structure is not individually eligible for listing in the National Register of Historic Places, but is a contributing element of the Delaware, Lackawanna & Western Railroad New Jersey Cutoff Historic District under Criteria A and C.

Physical Description: The reinforced concrete arch tunnel carries the railroad on a fill over a two-lane road. The span is a few hundred feet from the New Jersey end of the Delaware River Viaduct. The skewed barrel-arch tunnel is flanked by sloping, skewed wingwalls that retain the fill used to create the grade for the New Jersey Cut-Off. The deck is ballasted, but the right-of-way is overgrown with vegetation. The date of construction (1909) is inscribed in the spandrels at each end of the structure. The tunnel spans 33 feet and is 45 feet wide. A utility line runs under the bridge, but it is not physically tied to the structure.

Historical and Technological Significance: The New Jersey Cut-Off, of which this arched tunnel is a part, was built in 1908-1911 and is historically and technologically distinguished in the areas of engineering and transportation (Criteria A, C). The cut-off is an important engineering accomplishment of the early 20th century. The Delaware, Lackawanna & Western RR (DL&W) designed and built the line to improve the efficiency of train travel across the mountainous terrain of northwestern New Jersey in Warren, Sussex, and Morris counties. The design and construction of a railroad that rises and falls just eleven feet over its length of 28.45 miles while crossing the mountains and valleys of northwestern New Jersey is remarkable even today. The decision to use reinforced concrete exclusively for all structures along the route was a pioneering action that attracted the attention of the engineering profession. The railroad's use of reinforced concrete did much to prove the material to be as strong and durable as the engineers of the early-20th century had anticipated. The DL&W also made full use of the moldable qualities of the material, designing not just functional structures, but also aesthetically pleasing ones that enhance the beauty of the railroad.

Sixteen structures are included in the NJDOT Historic Bridge Survey, but other structures, including viaducts, tunnels, and stations, were observed within Warren and Sussex counties. The structures not included in this survey appear to have integrity consistent with those bridges and tunnels that are included.

The New Jersey Cutoff is the culmination of over 55 years of efforts by the company to improve its route across New Jersey to New York City. The Delaware, Lackawanna and Western Railroad (DL&W), composed of a network of smaller railroads in Pennsylvania, New York and New Jersey, was formed in 1853 for the purpose of moving anthracite coal from the mining regions of northeastern Pennsylvania to market locations. It started from the merger of the Liggett's Gap RR and the Delaware & Cobbs Gap RR, which had been chartered and developed around 1850 by parties interested in carrying the coal to the Erie RR to the west and to the Delaware River to the east.

As the anthracite coal mining industry grew, so did the desire to increase the access to markets. In reaching to the east the DL&W needed a connection in New Jersey. They incorporated the Warren Railroad in the 1851 to carry trains from the Delaware River at Columbia (Warren County, NJ) to Central Railroad of New Jersey tracks in Hampton (Hunterdon County, NJ). From there the coal could be moved eastward to Elizabethport (near Newark, NJ). Commuters also traveled this route to get to New York City. In the late 1860s the DL&W became dissatisfied with the CNJ connections and sought their own access to the New York markets. In 1868 they leased the

Morris & Essex RR, which was developed in the 1830s and 1840s in Morris, Essex and Hudson counties and the 1850s in Warren County. The M&E crossed New Jersey from Hoboken to Phillipsburg on the Delaware River.

Though the DL&W controlled several railroads (like the M&E, Warren, Valley, etc.), each was operated separately until 1899, when new DL&W president William Truesdale centralized control of the company. This move allowed for increased efficiency for the railroad as a whole. In addition to the reorganization, Truesdale undertook an ambitious plan to modernize the routes (All background information gathered from Taber, 1977).

In seeking a more efficient, less circuitous route to replace the 1860s Morris & Essex Railroad right-of-way, the DL&W considered three plans to build a completely new route (Taber and Taber, 1980:34-36). The plan chosen was a completely new line that would include massive cuts and fills to virtually eliminate grade changes. The existing line was nearly 40 miles long, had 57 curves comprising almost 13 miles of track, and a maximum grade of 60.2 feet per mile with a total rise and fall of 248 feet. The new layout, known as the New Jersey Cut-Off, limited the number and degree of curves and saved over 11 miles of track from the circuitous old line. This was the most expensive choice, costing $11,065,511.43 when completed (Taber and Taber, 1980:39), but the anticipated benefits for the railroad outweighed the cost.

Beginning in 1908 and under the direction of DL&W Chief Engineer George Ray, layout and design of the cut-off began. The line was to be 28.45 miles long, with a total rise and fall of just 11 feet and less than 5 miles of curved track. The new route would require 73 structures, including two massive viaducts, twelve overhead highway bridges and numerous crossings of roads and minor watercourses. Over 14 million cubic yards of both cut and fill were needed to create the relatively flat crossing of the hills and valleys of northwestern New Jersey (Taber and Taber, 1980:36).

Mr. Ray decided that reinforced concrete would be used for all structures along the route. This was the first time such a decision was made, causing the nickname of the "reinforced concrete railroad" to be used by the engineering profession when discussing the cut-off (Taber and Taber, 1980:36). Reinforced concrete was a state-of-the-art building material with yet unknown ultimate capabilities. It was thought to be as strong and durable as stone, and seemingly more permanent than wood or even steel.

Uncommon methods were used for the construction of the fills along the route. While the traditional method of building a wooden trestle to run dumping trains on was used for most fills, tracking was hung from suspended cables for the fills of greater magnitude. Dumping trains would carry fill onto the suspended tracks and dump the fill material from there. Most of the fill used on the cutoff was taken from the many cuts that were made, but even that was not enough. The DL&W bought 760 acres of farm land from which the contractors could dig additional fill. Five million pounds of dynamite was used to make the cuts. The Pequest Fill (Milepoint 55.85, Green Township, Sussex County) was the largest along the cut-off and in 1908 was claimed to be the "largest railway embankment ever made" (Engineering News, 1908:72). It was over 3 miles long and was up to 140 feet high. Over 6.5 million cubic yards of fill were necessary to reach the proper grade on this fill (Taber and Taber, 1980:36).

The DL&W chose to use similar structures for similar uses along the line. Where highway bridges were needed to cross their tracks, they designed reinforced concrete deck arch bridges, a bridge type that was capable of relatively long spans while providing dynamic and graceful forms. At least eleven deck arches were built in New Jersey, (1900G12, 1900G13, 1900K07, 1900C17, 2153166, 2153165, 2153164, 2153163, 2153162, 2153161, 2153160), all of them single span structures with one of two types of balustrades. Though design adjustments had to be made for roadway alignment and foundation conditions, the deck arch bridges are very similar structures.

Reinforced concrete arch tunnels were constructed where the cut-off crossed over roads or small waterways. These structures often supported high fill embankments as the cut-off crossed a valley. Over 35 of these structures were built along the line, and several of them are included in the Historic Bridge Survey (Wasigan and Simpson roads in Warren County, 2117152). Slab-roofed tunnels and box culverts were also built to carry the right-of-way over roads and streams.

The largest structures along the line were the two multi-span viaducts; the Delaware River Viaduct (2114159) and the Paulins Kill Viaduct (Milepoint 70.63, Knowlton Twp.). Both are open spandrel arch bridges that span valleys and larger water courses. The 9-span Delaware River Viaduct crosses the river as well as the highways that parallel it on both sides. It is 1,450 feet long and carries trains 65 feet above the river. The nine span structure has seven open spandrel arches and two deck arch approach spans on the Pennsylvania end. The 7-span Paulins Kill Viaduct in Hainesburg (Warren County) is 1100 feet long, but it is more graceful and magnificent as it rises 115 feet above the valley floor. It passes over the Paulins Kill River, the New York, Susquehanna and Western Railroad and the valley they run through. It was the most impressive structure on the DL&W main line prior to the building of the Tunkhannock Viaduct in Nicholson, Pennsylvania, completed in 1915.

Around the turn of the century, reinforced concrete arches were generally limited to relatively short and often single span bridges. The dead load carried by the arches was reduced with the introduction of open spandrel arches. The lighter structures were capable of longer spans and more aesthetically pleasing large bridges. The Walnut Lane bridge (1906-8) over Wissahickon Creek in Philadelphia was a forerunner of the type, though it used virtually no steel reinforcement in the two ribs (Condit, 1961:198). The use of reinforcement made the possibilities even greater. Under Ray's direction, the length and number of spans increased to create massive structures that dominated the landscape.

The New Jersey Cut-Off was divided into sections for bidding. Seven contractors were each awarded one section of the line, including contractors from as far away as Billings, Montana and Roanoke, Virginia. Each contract included all clearing, grading and masonry construction (Wheaton, 1908).

In addition to its engineering significance, the railroad right-of-way ranks historically as one of the most significant in the state, owing to the impact moving coal across the state had on the development of transportation systems within New Jersey. The Lehigh Valley Railroad played a significant role in the development of transportation and transportation-driven development in the northern half of the state, and the cut-off stands as one of the most ambitious remnants of the coal era in the state.

In summation, the viaducts, tunnels, overpasses, cuts, and fills on the New Jersey Cut-Off (1908-1911) form part of a unified design that was, and still is, one of the most remarkable engineering achievements of the early 20th century in the region. Furthermore, the New

Jersey Cut-Off is one of the most visible remnants of the DL&W, and is illustrative of the history of one of the largest movers of coal that contributed to the transportation-driven economic growth of the northern half of the state. The New Jersey Cut-Off is a significant part of the western New Jersey historic landscape and transportation systems.

Boundary Description and Justification: The significance of the structure is based, in part, on its historic association and physical connection with a right-of-way that is both historically and technologically important. In New Jersey, the potential historic corridor appears to be limited to the railroad right-of-way. The potential historic corridor is approximately 28 miles long stretching from the Delaware River to the eastern junction at Hopatcong, Morris County. The New Jersey Cut-Off's western junction is in Slateford, Pennsylvania on the west bank of the Delaware River. The entire route and all its related structures were not surveyed as part of this project, but those portions of the route that were surveyed or observed as part of the 1991-1993 Historic Bridge Survey have integrity of setting and original design and appear to representative of the overall state of preservation and completeness of the route in Sussex and Warren counties.
