New Jersey Division
With
Modifications based on Consultation between
The New Jersey Department of Environmental Protection
Historic Preservation Office,
The New Jersey Department of Transportation, and Others

Survey - September, 1994
Database Modifications 2001

Introduction

The 1987 Surface Transportation and Uniform Relocation Assistance Act mandated that each state conduct a survey of all bridges on and off the system to determine their historicity. In response, NJDOT hired A. G Lichtenstein & Associates, Inc. to conduct the necessary survey and make recommendations about the eligibility of each bridge for listing in the National Register of Historic Places. For the purposes of the survey, NJDOT=s definition of a bridge as a structure 20 feet or greater in length was adopted and an end date of construction of 1946 was chosen.

The development of historic contexts for evaluating the bridges; collection of survey data; analysis; and the formulation of recommendations about eligibility were completed during 1991-1994. Consultation with the SHPO on elements of the survey was initiated as early as the fall of 1992, and after review by NJDOT Bureau of Environmental Services and FHWA NJ Division Office staff, sections of the survey report and data forms were transmitted to the SHPO for review and comment. By it=s conclusion, the survey included data forms on 2,065 structures.

The Historic Preservation Office provided comments on the entire survey by letter of June 30, 1995. These comments addressed approximately 600 structures and were silent on 1465. During the fall of 1995 staff from Lichtenstein, NJDOT and the SHPO worked to resolve issues associated with the survey. At the conclusion of that effort agreement had been reached [but not formalized] on approximately 2,000 of the bridges. Over the past few years, NJDOT has renewed its efforts to bring the survey to conclusion by resolving outstanding issues on individual bridges. This effort, required to bring closure to the survey and as an initial step in developing an analysis of whether individual bridges could be preserved and a plan for doing so when possible, was completed in March of 2001. Since then, information has been added to the data base about alterations to the bridges [demolitions, rehabilitations, significant alterations, etc.], status of projects involving bridges listed in the survey when available [project planning has been initiated, memorandum of agreement has been executed, etc.], and additional Section 106 consultation references as available to the database team. Not all of this information will appear on the forms which can be viewed in the Adobe Acrobat format. Information pertinent to project status becomes dated immediately and is included as a comment field only in the database, which forms the basis for the forms. Descriptive text and other information [including an introduction, description of methodology, narratives on the development of transportation networks and the evolution of bridge building technology in NJ County summaries, bibliography, etc.] from the original survey report are also available in the Adobe Acrobat format.

The information included in this database is only useful if it is maintained. Please provide information about any corrections or additions needed to NJDOT=s Bureau of Environmental Services Historic Bridge Database Team as soon as you are aware of them. Changes will be incorporated periodically.

Data Form Design

The data form displayed in the NJHBD [Figure 1] has been modified slightly from those included in the 1995 survey for the purpose of clarity and including additional information. For example, the survey was comprised of an initial survey form and, for those structures, which were recommended as being eligible, a second Along form@ which provided additional descriptive information. These two forms have been combined into a single data form. The fields on the NJHBD form are described as follows:

Structure
Each bridge under state jurisdiction has been assigned a unique 7-digit number. The first two digits are a county code, and the five-digit suffix is a sequential route code for state bridges and often a variation of the old county numbering system for county-owned spans. All NJDOT records relevant to a particular bridge are filed by this unique number. A search on the structure number will let you know immediately if the bridge was included in the survey.

County
The county in which the bridge is located, or, in the instance of a joint-county span, the county, which assumes responsibility for the structure.

Owner
Governmental entity, agency, or corporation that owns the bridge. APrivate@ refers to a private owner or bridge commission. ARailroad@ is a generic entry indicating that a railroad company owns it, but not necessarily which one. ANJDOT@ refers to state-owned bridges.

Milepoint
State highways are measured west to east, or south to north from the 1) State line, or 2) origin of the route. Milepoints (referred to mileposts on railroads) are measured to the nearest hundredth of a mile.

Name & Feature Intersected
Name(s) of feature(s) carried and crossed

Facility
Name(s) of feature(s) the bridge carries. Local nomenclature is included in parenthesis.

Township
Local civil division where the bridge is located.

Type
A standardized entry based on a list of all bridge types found in the state [Figure 2].

Design
A standardized entry based on a list of bridge type designs found in the state [Figure 2]. Design assists with better identifying bridges with similar physical characteristics, such as the various trusses or concrete reinforcing systems.

Material
A standardized entry based on a list of the material of the primary members [Figure 2]. Spans are typed by primary material. When it is not known for certain if a span is steel or cast or wrought iron, Ametal@ is used.

Spans
Total number of spans.

Length
The backwall to backwall overall length of the bridge.

Width
The fascia-to-fascia width of the bridge

Construction Date
Date of erection. Circa dates are entered with Aca.@ after the year.

Alteration Date
Date(s) of significant alteration(s) that affect the appearance of span. Demolition dates are also included. Circa dates are entered with Aca.@ after the year.

Source
Source upon which the date(s) of construction/alterations(s) is/are based. In some instances Asource@ also refers to the source of historical data. ASTYLE@ is the convention used when the date is based on the physical evidence of the structure itself. ANJDOT@ refers to the date provided in the NJDOT structure database. That date was used when it was confirmed by physical evidence and research.

Designer/Patent
Identifies who designed the bridge or who patented the design or construction details. ANJ STATE HWY DEPT BRIDGE DIV@ is the convention used to identify bridges designed by the state highway department bridge engineers. AUNKNOWN@ was entered when research failed to identify the designer/patent. If no designer/patent was researched, then the category was left blank.

Builder
Identifies the person or company that actually built the span. When no research was conducted to identify the builder, the category was left blank. If research was conducted and no builder was identified then AUNKNOWN@ was entered.

Setting/Context
Surroundings and historic contexts are an important part of the National Register evaluation process. Frequently a bridge is found eligible because it is located in an identified potential, eligible, or listed historic district. For example, it might contribute to an historic context defined on the basis of industrial development or community planning. It could also be an area that once had historic significance but has been so altered that the significance has been lost. The bridge might be newer than it historic setting and therefore not contribute to it unless it is individually eligible. Individually eligible bridges also contribute to an historic district even if it does not relate to the significance of the district. Or, the span could be isolated in a setting surrounded by woods or fields. This category was defined to explain and assess the environment of the span as a means of better supporting the National Register recommendation. Because of space limitations, sometimes historical data, especially information about the road itself, was included in this category.

1995 Survey Recommendation
Provides the recommendation of the 1995 Historic Bridge Survey compiled by A.G. Lichtenstein & Associates, Inc. of whether the structure appears to meet the criteria for inclusion in the National Register of Historic Places. It is a studied and carefully considered opinion based on all of the information gathered statewide during the field work, research, and internal review phases of the survey. It reflects the perspective of historians and engineers. The process for reaching this recommendation is described in detail in the survey report and should be consulted by the reader. The recommendations of the survey do not necessarily correlate with the comments of the SHPO on the survey. Both are included in the database for the information of the users.

Consult Status
Describes the results of the most recent consultation with the SHPO in the context of the historic bridge database. Consultation comments made in the context of project specific discussions since the time of the survey have been included as available to the database team. The information included in this category is comprised of 1) the opinion offered by the NJ Historic Preservation Office on the survey results and/or any previous opinions offered by the Office on the individual eligibility of the structure to be listed in the National Register [findings include

AIndividually Listed@, AIndividually Eligible@, and ANot Individually Eligible@]; 2) the identity of any bridges and districts which are potentially eligible, eligible, or listed in the National Register at the location of the structure, with the date listed properties were actually listed in the Register [For example, AListed. South Randolphville Road Bridge. 09/17/1999"] ; 3) and an indication of whether the bridge is non-contributing, may contribute, contributes to the identified historic district, or has not been rated [For example, APotential Union County Park System Multiple Property nomination, May contribute@]. Since an analysis of the potential for each bridge to be within an historic district and evaluations of contributing/non-contributing status were not elements of the 1995 survey this information is not considered to be comprehensive and is included only when available to the database team. The term APotentially eligible@ in this context indicates there is recognition on the part of the HPO and the NJDOT that the area has either some historic significance or architectural character, which must be evaluated, to determine if an historic district indeed exists at that location. AAgreed historic district@ indicates that there is agreement by the two agencies that an historic district exists at that location, however full definition of the significance of the district and delineation of it=s boundaries has not been initiated. Use of past tense, as in ABridge was individually eligible@, indicates that the structure has been demolished or sufficiently altered such that it is no longer individually eligible for listing in the National Register. Properties listed only in the New Jersey Register of Historic Places and not in the National Register are also identified in this section.

Consult Documents

Enumerates the basis for the findings listed in AConsult Status@ and may include, SHPO letters [survey comments and project specific consultation status], SHPO opinions, and formal Determinations Eligibility from the Keeper of the National Register.

Summary

A narrative that briefly describes the bridge and significant alterations, and justifies and explains the National Register recommendation.

Information

Includes an expanded physical description, statement of historical and technological significance, boundary description, and a selected bibliography. This information is provided only for those bridges which 1) appeared to be eligible either individually or as a contributing resource in a potential historic district [if that district was identified at the time of the survey], 2) were of questionable eligibility which needed additional research to resolve, or 3) are in a listed National Register Historic District and were evaluated as being contributing resources [at the time of the survey]. This information does not appear for those bridges whose eligibility had previously been evaluated [National Park Service/Keeper of the National Register or SHPO has previously rendered a finding; bridges listed in the National Register individually or as contributing resources within districts; multiple property resources; or bridges recommended as being non-contributing to listed National Register Historic Districts].

Photo

Identifies the roll and negative number of images of this bridge. The date in parenthesis is the month and year the bridge was field inspected and photographed. Photographic images and negatives are retained by NJDOT=s Bureau of Environmental Services. At least two black and white photographs were taken of each bridge showing an elevation and through view. In rare instances field conditions precluded obtaining an elevation view.

Revised By (Date)

Records when the structure was re-evaluated or the survey form was revised after the database was finalized.

Quad

Identified the USGS 7.5 minute quadrangle map on which the bridge is located. Dates of the maps vary. A copy of the section of the quad map with the bridge marked on it is also on file with NJDOT=s Bureau of Environmental Services.

Copies of the original survey forms as submitted in final copy are on file with NJDOT=s Bureau of Environmental Services.

DESIGNER/PATENT UNKNOWN **BUILDER** PUBLIC WORKS ADM.

SETTING / CONTEXT The bridge carries a single track of NJT's Atlantic City Line, former Pennsylvania Reading Seashore Line, over two-lanes of US 9. The right-of-way was originally developed by the Camden and Atlantic Railway in the 1850s, but above grade crossings were not systematically added until the first decades of the 20th century. The bridge is near the intersection of US 9 and US 30; the surroundings are heavily developed with commercial properties.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed, single-span ballasted-deck steel thru girder bridge with floor beams has scored concrete abutments and concrete end posts at the ends of the girders. The bridge was built in 1939 as a New Deal era grade elimination project by the Federal Works Agency, Public Works Administration. The bridge is a representative example of a common railroad overpass bridge type, and is not historically or technologically distinguished.

DESIGNER/PATENT STRAUSS BASCULE BRIDGE COMPANY **BUILDER**

SETTING / CONTEXT The bridge carries two-lanes of traffic over Nacote Creek south of its confluence with the Mullica River. The bridge is located in a broad wetlands and coastal meadow. A number of 20th-century residences are nearby, some of them built against the creek with timber pile pier foundations. The bridge has a wood frame tenders house, and next to the southern approach a wood frame outhouse.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 02/01/80

SUMMARY The bridge consists of a single-leaf Strauss bascule main span and 16 timber stringer approach spans. The superstructure of the main span is a deck girder with articulated counterweight. The bridge has had repairs to its substructure, the counterweight has been gunited, and the operating mechanism rebuilt (1955). The bridge is 1 of 4 1920s Strauss bascule bridges in the county, it is probably the least technologically distinguished because of its standard design and short 40' span.

INFOR MATION

Bibliography:
Atlantic County. County Engineer's Office. Bridge Cards. 1922.
New Jersey Department of Transportation. Bridge Plans and Files.

Physical Description: The main span of the US 9 over Nacote Creek bridge is an operable single-leaf Strauss bascule with underneath counterweight. The superstructure consists of two deck girders with floor beams and stringers. The girders measure 40' from trunnion to toe, and taper from approximately 5' depth at the main trunnion to 2'8-1/2" depth at the toe. The counterweight is concrete in a metal frame connected to the end of the bridge girders by counterweight trunnions. The counterweight has been sprayed with gunite. The main trunnion is supported by steel posts of channels with lacing. The main trunnion posts are supported on a concrete pier while the toe rests on timber pile bents. The main span has pipe railings and steel grid deck. The main span was originally operated manually with a capstan, but in 1955 an electric motor was added. The electric motor was installed below the superstructure on a steel platform, and the gearing and shafting rehabilitated to accommodate the new power source. The operating mechanism is engaged from a single-bay, wood frame operator's house on the bridge's southeast elevation, also added in 1955.In 1961 the steel grid deck was installed replacing a wood deck.

The bridge has timber stringer approach spans, 7 to the north of the main span and 8 to the south. The timber stringer spans rest on timber pile piers with cross bracing. The approaches have a wood railing with outriggers for support. Although reconstruction records have not been located, it is most likely the approach span members have been replaced more than once since the bridge's original construction. On the upstream side of the southern approach is a wood-frame tenders house used by the bridge tenders for a place to rest and store their belongings. The tenders house is not shown in the plans and may have been added at a later date. An unusual feature of the bridge is a wood-frame outhouse next to the southwestern abutment. The bridge has an older set of manually-operated lattice rail gates, probably original to the bridge, but new automatic gates have been added.

Historical and Technological Significance: In 1922 the Nacote Creek bridge was built by the county with state funding as part of the improvement of the newly-created NJ Route 4, later redesignated US 9.The single-leaf Strauss bascule bridge was designed by the Strauss Bascule Bridge Company of Chicago, Illinois, the nation's foremost engineer of movable bascule bridges. It is one of four documented surviving movable 1920s Strauss bascule highway bridges in Atlantic County. Due to alterations to the operating mechanism, and the application of a standard Strauss design for a relatively short-span movable crossing, the US 9 over Nacote Creek bridge is not the most historically or technologically distinguished of the county's movable spans. It does not have National Register significance.

SETTING / CONTEXT The bridge carries 6-lanes of US 30 over Beach Thorofare in the tidal meadows west of downtown Atlantic City. The surrounding area is undistinguished with billboards, parking lots, and a scattering of commercial establishments along the highway. The bridge was designed just before the outbreak of WWII, but its completion was interrupted by the war.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-leaf bascule bridge has 6 encased stringer approach spans. The 80'-long bascule has a deck girder superstructure, underneath counterweight, and operators house. The bridge is the newest of at least 5 surviving pre-1946 bascule spans in the county, it has no distinctive details or features. Much of the machinery was replaced and the superstructure rehabilitated in 1989. The operators house was also enlarged. The altered bridge is not technologically noteworthy.

SETTING / CONTEXT The 2-lane bridge spans Babcocks Creek east of downtown Mays Landing. West of the bridge is a municipal park and marina. The bridge is within the boundaries of the Mays Landing Historic District, which includes a number of nearby 19th- and 20th-century residential structures.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Mays Landing Historic District. 08/20/1990. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 6-span timber stringer bridge has timber pile substructure and wood deck with asphalt road surface. Two-high beam guide rails have been added. Dated 1921 by NJDOT, the bridge appears to have been rebuilt inkind within the past 25 years. No plans or records have been located, but based on its present appearance, it appears that it was rebuilt after the 1837-1935 period of significance of the Mays Landing Historic District. The span is too new to be evaluated as contributing.

SETTING / CONTEXT The 2-lane bridge spans the Great Egg Harbor River on the western side of downtown Mays Landing. The bridge lies within the boundaries of the Mays Landing Historic District, which includes 19th- and 20th-century houses on both sides of the river from the bridge. The river is navigable and east of the bridge is a marina.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Listed. Mays Landing Historic District. 08/20/1990. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1928 deck multi girder bridge consists of three encased plate girders with concrete slab deck, cantilevered sidewalks, concrete balustrades, and scored concrete abutments. The bridge was built as part of the reconstruction of NJ 48, redesignated US 40 in the early 1950s. It lies within the period of significance (1837-1935) of the Mays Landing Historic District, and should be considered a contributing structure that reflects the impact of highway improvements on the community.

INFOR MATION

Bibliography:
Office of New Jersey Heritage. National Register
File. Mays Landing Historic District. 1990.

Physical Description: The 77'-long one-span bridge is composed of three encased built-up deck girders supported on a concrete substructure with flared wing walls that are scored. The cantilevered sidewalks have concrete balustrades with paneled posts. Wood sheet piling has been added as scour protection to the abutments, and beam guide rails separate the roadway from the sidewalks.

Historical and Technological Significance: The concrete-encased multi deck girder bridge is not individually technologically distinguished, but it is historically significant as a contributing resource to the Mays Landing Historic District, listed in 1990.The bridge was not rated in the nomination, but it was built within the 1837 to 1935 period of significance of the district. The district is eligible under Criterion A of the National Register for its significance in architecture, industry, politics/government, and community development. US 40 and NJ 50 is the main road through the community that was designated as the county seat in 1837, and the road has had a dramatic impact on the historic development of the district.

The bridge is a standard type and design used by the New Jersey State Highway Department throughout the state. It was built as part of the 1928 redevelopment of NJ 14, one of the original 15 state highway routes. NJ 14 went from Egg Harbor City to Cape May City by way of Mays Landing, Tuckahoe, and Cape May Court House. The designation was changed to NJ 48 in 1928. It became US 40 in the 1953 redesignation.

Boundary Description and Justification: The bridge is within the boundaries of the Mays Landing Historic District as delineated in the Mays Landing USGS Quad Map accompanying the nomination. The bridge including its superstructure, substructure, and right-of-way over the river is a contributing resource.

SETTING / CONTEXT The 2-lane bridge spans the abandoned right-of-way of the Pennsylvania Railroad's Pleasantville Section, originally developed in 1880 by the West Jersey Railroad. The bridge is located in the Mays Landing Historic District, and near the bridge are numerous contributing 19th- and 20th-century residences. Under the bridge is the former loading platform for the railroad, and just north an abandoned single-story, hipped roof, brick station house.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Listed. Mays Landing Historic District. 08/20/1990. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span encased steel stringer bridge has paneled parapets and a concrete substructure with arched piers. It was constructed in 1929 as a grade elimination project associated with improvements to NJ 48, and is a representative example of a bridge type used by the PARR for other overpasses. It falls within the period of significance of the Mays Landing Historic District (1837-1935) and is a contributing element reflecting both rail and road transport.

INFOR MATION

Bibliography:
Office of New Jersey Heritage. National Register File. Mays Landing Historic District. 1990.

Physical Description: The three-span bridge with concrete parapets is composed of encased rolled steel stringer spans supported on concrete abutments and concrete bents with arched struts and crash walls. The 1929 Pennsylvania Railroad station, a hip-roofed one-story brick building, is adjacent the bridge at the track level. It is not in use and the track is abandoned.

Historical and Technological Significance: The 1929 encased stringer overpass is not individually distinguished, but is a contributing resource in the Mays Landing Historic District, listed in the National Register in 1990 for its significance in architecture, industry, politics/government, and community development. The district is eligible under Criterion A. The period of significance is from 1837, when the town was designated the Atlantic County seat, until 1935. The overpass and adjacent station were constructed by the Pennsylvania Railroad as part of a grade elimination agreement in 1929. The Pennsylvania Railroad was successor to the West Jersey and Atlantic Railroad that initially developed the right-of-way to Mays Landing in 1880. Because the bridge is located within the district, is unaltered, reflects the historic rail and highway development of the community, and was built within the National Register nomination's period of significance, it is evaluated as a contributing resource.

Boundary Description and Justification: The bridge is within the boundaries of the Mays Landing Historic District as delineated on the Mays Landing USGS Quad Map accompanying the district nomination. The bridge including the superstructure, substructure, and right-of-way over the railroad line, is a contributing resource.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries a single track of ConRail's Linwood Section over 4-lanes and median of US 40 near downtown Pleasantville City. The surrounding neighborhood has mostly undistinguished 20th-century residential and commercial structures. The railroad right-of-way was originally developed in 1880 by the Pleasantville and Ocean City Railroad. In the 1930s, when the current bridge was constructed, the railroad was owned and operated by the Pennsylvania Railroad Company.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed 2-span bridge is a thru-girder with encased floor beams, ballasted deck, and concrete abutments and center pier. In 1934 the bridge was built as a grade elimination highway underpass during the widening of NJ 48 (current US 40). A chainlink fence has been attached to the bridge girders. The bridge is not associated with the historically significant period of development of the railway, and is a technologically undistinguished example of a common railroad overpass bridge type.

DESIGNER/PATENT PENNSYLVANIA READING RAILROAD **BUILDER**

SETTING / CONTEXT The bridge carries two lanes of NJ 54 over New Jersey Transit's Cape May Line and over Hospitality Brook. The bridge is located in the Pine Barrens near the US 322 intersection and a concrete pipe manufacturer. The railroad right-of-way was originally developed in 1890 by the Atlantic City Railroad as a branch line to Cape May. In 1933 the Atlantic City RR was consolidated under the control of the Pennsylvania-Reading Seashore Lines (PRSL RR).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 418'-long 8-span bridge consists of 2 skewed thru girder with encased floor beam spans, and 6 encased stringer spans. The thru girder spans rest on large single column concrete piers at each girder bearing, while the encased stringer approach spans have triple column piers, concrete abutments, and concrete parapets. Bracing has been added at several piers. The bridge is not historically or technologically distinguished, and is similar in design to other late-1930s PRSL RR bridge projects.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries 4 lanes of traffic over a small creek in the Pine Barrens. The bridge is near the intersection of NJ 50 and US 322, but the immediate surrounding area is otherwise undeveloped.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The original 1931 concrete slab bridge with concrete substructure has been significantly altered by widening with prestressed concrete beam additions on both sides of the bridge, and by the addition of concrete parapets with pipe railings. The alterations were part of the 1959 reconstruction of US 322. The bridge is a common type and is not historically or technologically distinguished.

CONSTRUCTION DT 1938 **ALTERATION DT** **SOURCE** PLANS

DESIGNER/PATENT PA-READING SEASHORE RAILROAD **BUILDER** PHOENIX BRIDGE COMPANY

SETTING / CONTEXT The two-lane bridge with sidewalks spans the abandoned & filled-in right-of-way of ConRail's Linwood Section, the former Pleasantville and Ocean City Railroad, established 1890. West of the bridge is the ONJH Somers Point Mansion (c.1725). The bridge does not lie within the Bay Front Historic District (c.1890-1935) which begins one block south. The area southwest of the bridge originally contained the railroad station and ferry, but the buildings have been removed for newer structures.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The thru girder with encased floorbeams bridge has a concrete substructure and cantilevered sidewalks with riveted steel plate parapets. It was designed in 1938 by the PRSL RR engineering department, and fabricated by the Phoenix Bridge Company. The parapets are the bridge's only technologically distinguishing feature and do not merit NR significance on an otherwise common example of a 1930s thru girder overpass.

SETTING / CONTEXT The bridge carries a single lane of traffic over Penny Pot Lake, a privately owned lake with 20th-century lakefront homes. The bridge is near the intersection of Eighth Street and US 322 in the Pine Barrens.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 11/22/95

SUMMARY The single-span bridge is a 6-panel rivet-connected Warren pony truss. County records indicate that in 1937 the bridge was moved to this site from an unspecified location and reassembled. Stylistically it dates from c.1915. The bridge has had repairs including new substructure and welded repairs, but it is one of fewer than five surviving metal truss bridges in southern New Jersey. Because the bridge is a rare survivor in the region and a representative example of a once common truss bridge type, it is technologically significant.

INFOR MATION

Bibliography:
Atlantic County. County Engineer's Office. Bridge Cards and Files. 1937.

Physical Description: The one-span rivet and square-head bolt connected Warren with verticals Pony truss bridge is supported on timber substructure. The span is traditionally composed of built-up box members for the top chord and inclined end posts. The verticals are closely spaced angles with lacing, and the diagonals are toe-up angles joined by battens. The built-up floor beams connect to the top chord and verticals by bolts. Replacement stringers carry a plank deck. The bottom lateral bracing is pin-connected eye bars. Alterations appear to be limited to minor reinforcing at the center panels of the bottom chord and a few lower panel points.

Historical and Technological Significance: The Eighth Street bridge (c.1910) is one of fewer than five surviving metal truss bridges in southern New Jersey. It is eligible under National Register Criterion C. It is a fairly complete example of a rivet and bolt-connected Warren with verticals truss that was very common around the turn of the century. Although metal truss bridges were never as numerous in the southern parts of the state as in the north, they played an important role in the region's highway development. Other surviving trusses in Atlantic County include Weymouth Road over Great Egg Harbor (01HML22, Hamilton Township, 1920) and Mays Landing-Somers Point Road over English Creek (01EH021, Egg Harbor Township, 1914). The latter bridge is significantly altered. In Cape May County the only known surviving highway metal truss bridge is Marshallville Road over Mill Creek (0500019, Upper Township, 1901). No metal truss bridges, exclusive of movable spans, are known to survive in Cumberland, Gloucester, Ocean, and Salem Counties.

The Eighth Street bridge was moved to this location in 1937. Its original location and name of fabricator are not documented in the County Engineer's records, but stylistically it dates from ca. 1910. Although the span does not display any distinctive details, it is technologically significant as a rare survivor of an important bridge type.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including the superstructure, substructure, and right-of-way over the river.

East of the bridge is the small 19th-century crossroads village of English Creek. The residential structures in the village have many modern alterations and additions.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1914 single-span 4-panel rivet-connected Warren pony truss has been significantly altered. In 1972 steel channels were welded to the lower chords and 16 timber piles driven to support the bridge. In 1991 intermediate piles were driven to independently support the floor beams, and masonry abutments reconstructed. The bridge no longer effectively functions as a truss and lacks integrity. It is not historically or technologically distinguished.

INFOR MATION

SOURCES: Atlantic County. Bridge Cards and Plans. 1914-1991.

PHYSICAL DESCRIPTION:
The 1914 rivet-connected steel Warren pony truss measuring 52' span from end-bearing to bearing has been significantly altered and no longer functions as a truss. In 1972 welded steel channels were added to the lower chord which had seriously deteriorated. At the same time, steel stringers were replaced and the span supported with the addition of timber pile piers. In 1991 further repairs were made to the bridge by the addition of intermediate piles to support each end of the truss's three floor beams independent of the truss. Also in 1991 the masonry abutments were reconstructed with concrete.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE
The Warren pony truss is a highly altered, yet representative example of a common early-20th century bridge type. The Mays Landing-Somers Point Road bridge over English Creek was designed by county engineer Alexander H. Nelson, and constructed by local contractor John H. Kahle. It is one of three known surviving Warren pony truss highway bridges in Atlantic County, and it is the least well preserved. The Weymouth Road bridge (01HML22, Hamilton Township, 1920) over the Great Egg Harbor River is a better example of the bridge type. Due to alterations and the fact that it is a standardized design, the bridge is not historically or technologically distinguished.

SETTING / CONTEXT The bridge carries two lanes of traffic over the Great Egg Harbor River next to Weymouth County Park. The park is located at the ruins of an early 19th-century iron furnace that ceased operations in 1862. The bridge is located north of the intersection of Weymouth Road and US 322. The area around the bridge and park is moderately developed with 20th-century residences.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel, rivet-connected Warren pony truss bridge a well-preserved example of an increasingly rare metal truss bridge technology in South Jersey. The bridge was built on standard specifications by a local contractor based upon designs approved by the county engineer. It is not within the historical period of significance of the adjacent iron furnace, but stands on its own as a rare representative example of a regionally important engineering achievement.

INFOR MATION

Bibliography:
Atlantic County. County Engineers Office. Bridge Cards and Plans, 1920.
New Jersey Department of Transportation. Bureau of Environmental Analysis. "Cultural Resources Survey for Weymouth Road and Bridge (Route 559)." 1983.

Physical Description: The 4-panel riveted Warren pony truss is 44'-long (c/c from end bearings) and is 7'3" high. The bridge is composed of rolled steel sections. The end posts and top chords are built-up box beams, and the diagonals, verticals, and lower chords are angles with battens. The floor beams are I-beams attached at the lower chord panel points by gusset plates and riveted connections. The stringers are also I-beams inset into the floor beams with riveted stiffeners. The deck is wood plank with at least one layer of asphalt. The bridge has lower lateral tie rods. The abutments and wing walls are concrete. The bridge has a maker's plaque reading, "Atlantic County, 1920. Henry S. Kraus, Contractor."

Historical and Technological Significance: The Warren pony truss bridge (1920) is one of the best preserved metal truss bridges in southern New Jersey. It is eligible under National Register Criterion C. In Atlantic County only two other metal truss bridges, exclusive of movable spans, are known to survive: Eighth Street over Hospitality Brook (01BV007, Folsom Borough, c.1910), and Mays Landing-Somers Point Road over English Creek (01EH021, Egg Harbor Township, 1914). The latter is significantly altered. No metal truss highway bridges, are known to survive in neighboring Cumberland, Gloucester, Ocean and Salem Counties. In Cape May only one metal truss bridge survives (0500019, Marshallville Road over Mill Creek, Upper Township, 1901) Metal truss bridges were never as numerous in South Jersey as in the northern part of the state, yet they played a significant role in the improvement of local highways in the late-19th and early-20th century.

In Atlantic County at least 6 other Warren pony truss bridges similar to the Weymouth Road bridge are known to have been built in the first two decades of the 20th century. Like the Weymouth Road bridge, they followed a standardized Warren pony truss design prepared by the county engineer, and were usually constructed by local contractors. The Weymouth Road bridge is built upon plans prepared by county engineer Alexander H. Nelson and was constructed by Henry S. Kraus.

The county park adjacent to the bridge is on the site of the Weymouth Iron Furnace that operated from the early 19th century to 1862. From 1862 to 1887 the site was operated as a paper mill, but this too closed due to lack of financial success. The current bridge, while on the site of earlier bridges, is not historically associated with the development of the industrial site, and belongs to a period of road improvements that post-date the iron industry in South Jersey.

A 1983 NJDOT Bureau of Environmental Analysis report recommends that the Weymouth Road bridge be considered ineligible for inclusion in the National Register because it is a standardized design. If the bridge were located in a region with more numerous surviving trusses the ineligible status might be warranted, but given that the bridge is one of the only extant example of its type in southern New Jersey, eligible status is recommended.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including the superstructure, substructure, and right-of-way over the river.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span encased steel stringer bridge has pipe railings, a concrete substructure, and paneled arch concrete fascias with decorative keystones. In 1940 it was built as a WPA project. It is not within the period of significance of the Mays Landing Historic District (1837-1935). Steel stringers are a common bridge type, and the bridge is not historically or technologically distinguished.

SETTING / CONTEXT The bridge carries two lanes of traffic over the Mullica River between Atlantic and Burlington Counties. The southern bank of the river is undeveloped wetlands. The northern bank is the village of Green Bank (c.1780-1930). The village is not well preserved, and it does not have the integrity to be a National Register district.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Mullica River Chestnut Neck NJ Register Listed 10/01/1976. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-leaf Strauss overhead bascule bridge has 16 timber stringer approach spans and bulkheaded causeway. Original plans for the bridge reveal that it retains its overall integrity of design, although some minor alterations have been made to the railings, operating mechanism, locking mechanism, and substructure (c.1950). The bridge opens to navigation and is tended by an operator. It is significant both for its engineering and for its contribution to the historic character of Green Bank. The village is too altered to be a potential historic district.

SETTING / CONTEXT The bridge carries two lanes of traffic over a broad reach of Nacote Creek in a coastal area of Atlantic County. The town of Port Republic City lies on the northern bank of Nacote Creek. The bridge and road form one of the boundaries of the Port Republic Historic District (c.1760-1946), which includes residential and commercial structures on both sides of the creek. The town's areas of historic significance include earlier water power sites and maritime commerce.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Port Republic Historic District. 05/16/1991. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge consists of a 7-panel Warren pony truss center-bearing swing span and 23 timber stringer approach spans. The truss is a rare example of a bridge fabricated by the New Jersey Bridge Co. of Manasquan, New Jersey, and although the approaches and substructure have been rebuilt, the truss itself retains its integrity. It is the only surviving example of a highway swing span in Atlantic County, and contributes to the historic character of the Port Republic Historic District (1760-1946).

INFOR MATION

Bibliography:
Atlantic County. Division of Engineering. Bridge Plans and Records. 1904-1990.
Manasquan, New Jersey. Compiled by the Townfolk for the Diamond Jubilee under the Sponsorship of the Manasquan Chamber of Commerce. 1962.

Office of New Jersey Heritage. Port Republic Historic District Nomination. 1991.

Physical Description: The Smithville-Port Republic Road bridge is a 24 span bridge. The main span is a center-bearing Warren truss swing bridge. The approach spans, 11 to the north and 12 to the south, are timber stringers on timber piles. The manually-operated bridge may be opened to navigation with 8 hours notice to the county.

The movable span is a 7-panel riveted Warren with verticals pony truss composed of rolled steel members. The upper chords are built-up box beams with riveted cover plates, and the lower chords, diagonals, and verticals are angles with battens. The floor beams are built-up beams and the stringers I-beams. The bridge has a wood deck with asphalt surface. The bridge is opened to navigation manually by a capstan which engages the rack and pinion that moves the span. The swing span is center-bearing with a box-shaped system of girders with four balance wheels over the center pier. The swing span's end bearings rest on stone piers capped by concrete risers. The center pivot pier is an approximately 20' diameter concrete filled metal shell. A beam guide rail has been added to the truss.

The approach spans are timber stringers resting on cross braced timber pile bents. The approach spans have beam guide rails. No significant repairs have been made to the superstructure of the swing span, however, it is in an increasingly deteriorated condition with rusting evident and with visible twisting of the vertical and diagonal members in the second panel in from the southwest and northeast corners of the truss. In 1952 the substructure of the main span was raised by concrete additions to provide greater navigational clearance. In 1985 the deck and some of the stringers were replaced due to damage from a heavy truck. The timber stringer approach spans have been rebuilt numerous times in the bridge's history. County records indicate that they were reconstructed in 1924, 1948, 1952, and 1976.

Historical and Technological Significance: The manually operable center-bearing Warren with verticals pony truss swing span bridge was built in 1904 and fabricated by the New Jersey Bridge Company of Manasquan, New Jersey. It is located within the Port Republic Historic District (1760-1946) but was not rated in the National Register nomination. It should be evaluated as a contributing structure representative of the town's historic orientation toward the water and the important role maritime commerce played in the economic development of the town. The district is eligible under Criterion A of the National Register. In addition to being within the historic district, the bridge is the only known surviving swing span highway bridge in Atlantic County, and is one of less than six documented bridges by the New Jersey Bridge Company, an in-state fabricator. The swing span truss has not been significantly altered although the approach spans and substructure have been repaired and reconstructed over the years. No original plans for the bridge have been located at the county engineer's office.

The New Jersey Bridge Company was founded at Manasquan in 1890, and it was active until 1907 when financial difficulties caused the company to close. Messrs. Wyckoop and Baly, formerly of the Canton Bridge Works of Ohio, established the bridge fabrication shops adjacent to the railroad tracks in Manasquan. They marketed their bridges nationally, and it is known that they produced spans for Grand Rapids, Michigan (1903 North Park Bridge, a Pratt thru truss) and Portland, Maine (1906-07 Vaughn Bridge, a large rivet-connected swing span). In New Jersey at least two other movable New Jersey Bridge Company bridges are known to survive: the 1905 New Bridge thru truss swing span over Alloways Creek in Salem County (1701399), and the 1903 riveted Warren pony truss swing span over Rancocas Creek in Burlington County (03C4004). Swing spans were a popular late 19th century movable bridge technology but lost favor in the early 20th century to bascule bridges that offered faster opening and closing times and improved channel clearances.

In 1989 the bridge was dedicated to Alton M. Bowen, a locally prominent citizen of Port Republic who served as Mayor and City Council President for over sixty years. A commemorative plaque mounted on a large boulder is situated at the bridge's southern approach.

Boundary Description and Justification: The bridge is within the defined boundaries of the Port Republic Historic District as delineated in the USGS Quad Map accompanying the district nomination. The bridge superstructure, substructure, and right-of-way over the river are contributing resources to the historic district and within the district's period of significance (1760-1946).

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The brick jack arch stringer bridge supported on ashlar abutments was widened to both sides in 1953 with a concrete substructure supporting reinforced concrete T beams and concrete parapets. In 1963 the T Beams at one side were replaced with a reinforced concrete slab. A concrete toe wall was constructed at the south abutment. This altered bridge is one of over six stringers with brick jack arches in the county, and is not distinguished historically or technologically.

SETTING / CONTEXT The bridge carries a 2-lane urban connector over a major river between downtown Hackensack and Bogota. A concrete batching plant and the Bergen County Court House are in close proximity to the bridge. The S.S. Ling Submarine is moored just upstream of the bridge. This bridge is the upstream-most movable span still in operation on the Hackensack River.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The center-bearing swing-span Warren thru truss bridge with two steel deck girder approach spans is supported on a concrete substructure. Alterations such as reinforcement of the lower chords in 1974 and repairs to floorbeams and stringers have not compromised the integrity of design. The bridge is one of the only remaining operable through truss swing spans in NJ. It was built by a prominent local contractor, and is a technologically significant example of a rare surviving bridge type.

INFOR MATION

Bibliography:
Bergen County Engineers Office. (Plans).
Bergen County Division of Cultural and Historic Affairs. Folio 408.

Physical Description: Constructed in 1907, the 317' long center-bearing through truss swing-span bridge supported on a concrete substructure has steel deck girder approach spans. The truss has riveted connections, and the diagonals and top and bottom chord members are composed of back-to-back channels with lacing. The verticals are 4 angles with lacing. The operating mechanism of the swing-span has undergone several maintenance repairs and remains operational. The operators house, set on the upstream corner of the Hackensack side of the river, does not appear to date to the original construction, however no documentation of the house was found. The original decorative metal railings are intact at the approach spans but chain-link-fences were placed along the sidewalks on the swing-span in 1974. The timber fenders at the swing-span piers have been reconstructed several times. In 1950 the original concrete jack arch deck was replaced with a reinforced slab and the stringers were encased. In 1974 the truss lower chord was reinforced for its full length, plates were added at the bottom flanges of the end floor beams, and new stringer seat angle connections were added at the floor beams.

Historical and Technological Significance: The riveted through truss bridge is one of several swing-span crossings of the Hackensack River, an important navigable waterway instrumental in the growth and industrial development of Bergen County. Constructed in 1907, the span replaced an earlier swing-span bridge. The builder, F.R. Long Company, was a New York firm that was a prolific bridge contractor in Bergen County, and it incorporated in New Jersey in 1899 moving its major operations to Hackensack at a site adjacent to the bridge. Although the span has undergone some alterations, it is a well-preserved and operational example of the swing-span trusses over the Hackensack River built by a prominent contractor in Bergen County. 02000I1 spanning the Passaic River in Rutherford Borough is also a well-preserved example of an operational swing-span through truss in the county.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane collector road with a turn lane and sidewalks over a small stream set in Demarest Park. A concrete spillway located just upstream from the bridge forms a duck pond. The Demarest train station constructed in 1872 is adjacent to the park, and the town of Demarest lies just beyond the station.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The brick deck arch bridge supported on ashlar abutments was widened to both sides in 1911 to accommodate sidewalks. Stringers and brick jack arches support the sidewalks flanked by stone parapets topped with the original 1909 coping stone. The railing is no longer in place. Virtually unaltered since 1911, the span combines two turn-of-the-century bridge types. A distinguished example of an uncommon bridge type, it is historically and technologically significant.

INFOR MATION

Bibliography:
Bergen County Engineers Office. microfiche 9B 9 160. Bridge Card 26-2.

Physical Description: The 32' span brick deck arch bridge supported on ashlar abutments was constructed in 1909 and was widened with steel stringers and brick jack arches on ashlar abutments in 1911. Three jack arch bays with 3/4" tie rods were added to each side of the bridge to accommodate sidewalks. The original coping stone was reused with Cast Iron Newel post and railing similar in design to Chester B. Albree's "Florence" pattern as specified on the widening plans. A stone parapet topped with presumably the original coping stone has since replaced the railing. With the exception of the railing, the bridge spanning the Tenakill Brook in Demarest Park appears to be unaltered since the 1911 widening.

Historical and Technological Significance: The brick deck arch bridge is a well-preserved example of an uncommon bridge type located in a park setting adjacent to the 1872 Demarest Train Station, which was included in Bergen County Demarest Historic Sites Survey. Although the original bridge has been altered, the brick jack arch widening is a good example of a prolific turn-of-the-century county type that was eventually replaced by the reinforced concrete deck. The span, constructed in 1909, is significant because it is well-preserved, and it is the only example of a brick deck arch bridge in the county.

DESIGNER/PATENT WISE & WATSON, PASSAIC **BUILDER** F. R. LONG & COMPANY

SETTING / CONTEXT The bridge carries a 2-lane city street and sidewalks over a major river in a densely populated mixed commercial and early 20th century urban residential area. The Bergen-Passaic County line passes through the bridge. Located between 2 turn-of-the century urban centers, a bridge has spanned the Passaic River at this crossing since 1868.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span thru girder bridge is supported on ashlar abutments and piers. Alterations include welded plates added to the girder webs and concrete caps placed on the substructure units. The floorbeams and hanger supports were replaced 1989. The well-preserved span is significant because it is a long example of its type and is the earliest documented thru girder bridge in Bergen County.

INFOR MATION

Bibliography:
Bergen County Engineers Office. History of Passaic and Its Environs, by William W. Scott, Lewis Historical Publishing Company, Inc., New York 1922.
Bergen County Division of Cultural and Historic Affairs. Bergen County Historic Sites Survey, City of Garfield, 1980-1981.

Physical Description: The 233' long 3-span through girder with floor beams bridge supported on ashlar abutments and piers was built in 1898 replacing a bridge over the Passaic River known as the "Iron Bridge". The bridge is composed of built up riveted plate girders and built up floor beams. In 1989 a major rehabilitation of the span included replacing the deck, stringers and repairs to the floor beams. An earlier rehabilitation included the addition of welded plates to the web of the girders at deck level. Concrete caps were added to the masonry substructure. The alterations do not mar the integrity of the original design.

Historical and Technological Significance: The 1898 through girder bridge is an early and long example of the type. Spanning the Passaic River between the cities of Garfield and Passaic, the first bridge at this crossing was constructed in 1868 following the 1866 construction of Passaic Street from Lodi through Garfield to the Passaic River. The builder, F.R. Long Company, was a New York firm that was a prolific bridge contractor in Bergen County, and it incorporated in New Jersey in 1899 moving its major operations to Hackensack. The engineers, Wise and Watson Company of Passaic, were important local bridge builders in the 19th century. An historically important crossing in the development of the cities of Garfield and Passaic and survivor of the flood of 1903, the bridge is technologically significant in that it is a long span and the earliest documented example of the multi-span girder bridge in Bergen County.

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a major river in a mixed commercial/industrial and urban residential area. The river forms the boundary between Bergen and Passaic counties. Post-World War II apartment buildings are located at the Passaic County side of the bridge. At the Garfield side is a factory constructed in 1892 by the Fritze Bros., a German chemical company, that appears to have been renovated in the 1970s.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span deck arch bridge supported on a concrete and stone substructure has decorative balustrades with vase-shaped balusters. The span has lost its visual integrity through deterioration and gunite repairs, and it is neither technologically innovative nor historically distinguished. Large sections of the balustrades are missing or damaged, and the fascia and intrados are spalled. A spall at the downstream end of one pier exposes stones covered with mesh reinforcement and gunite.

INFOR MATION

Bibliography:
Bergen County Engineers Office (Plans)
Bergen County Historic Sites Survey, City of Garfield, 1980-81.

Physical Description: The 3-span 306' long bridge supported on a concrete substructure is composed of 3 equal elliptical reinforced concrete arch spans each with a ' clear span and a ' rise. The span supports a 30.2' width 2-lane road and 2 sidewalks bounded by concrete balustrades with vase-shaped balusters. Several balusters have been repaired or replaced. In 1947 guide rail was added along the curbline, and in 1948 new concrete curbs were placed. The substructure was rehabilitated in 1949. Gunite was placed at the abutments, wire mesh reinforcement covered with gunite was added to repair the face of the piers, and the north end of the piers were repaired with steel angles and anchor bolts.

Historical and Technological Significance: The elliptical arch bridge is a well-preserved and long example of its type. A plaque on the bridge indicates it was built by CW Dean Company, a NY firm, in 1908. F.R. Long Company Engineers and Contractors prepared the plans for the bridge dated Aug. 1907. Another set of plans for a 3-span arch bridge dated May 1907 was prepared by Schwiers & Sutton Co. of NY but was not used for construction. F.R. Long Company, was a NY firm that was a prolific bridge builder in Bergen County, and it incorporated in NJ in 1899 moving its major operations to Hackensack, where the founder, Frank R. Long had a residence. The bridge spans the Passaic River, an important navigable NJ waterway, between 2 urban centers, Passaic and Garfield. On the Garfield side of the bridge stands the circa 1890s factory buildings of Fritzch Brothers, a German chemical company, that was one of the first modern manufacturing concerns to have a factory in Garfield. In 1903 the Heyden Chemical Company took over the plant and remained in operation until the company was seized by the U.S. Government in 1918. The bridge is significant as one of several crossings over the Passaic River that were important in the development of a major industrial and commercial area. The only pre-WW II multi-span concrete deck arch bridge in the county, the well-documented span is distinguished as an early and architectonic example of a multi-span deck arch bridge.

 # SPANS 1 **LENGTH** 78 ft **WIDTH** 30 ft

CONSTRUCTION DT 1927 **ALTERATION DT** **SOURCE** PLANS

DESIGNER/PATENT R. MCCLAVE, COUNTY ENGINEER **BUILDER** DANSEN CONSTRUCTION CO.

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a shallow river adjacent to Route 4 in a post-WWII residential neighborhood. The bridge is located next to the site of the extant Red Mill. According to a historic marker, the grist mill, built in 1745, was the site of raids and encounters during the Revolution. Aaron Burr was entertained here Christmas Eve in 1776. Washington and his men often passed here. Lafayette stopped here on his return visit to America in 1825.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete deck arch bridge has concrete balustrades and substructure. Exedrae are provided at the bridge corners. Much of the intrados has been patched and the balustrades have been repaired. Although the bridge is located at an historic site, it post-dates the mill and the activities that distinguished this area. Neither an early or innovative example of its type, the span is not technologically nor historically distinguished.

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a small stream in a wooded sparsely developed neighborhood of post-World War II single-family homes.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 4/30/91, Letter 6/30/95.

SUMMARY The concrete arch bridge was constructed in 1902 using the Monier reinforcement system. The span was widened on both sides in 1930 with concrete T beams on concrete abutment extensions. The sidewalks and balustrades were also added at that time. An example of a concrete arch bridge with a documented patented reinforcement system, the bridge was evaluated as historically and technologically significant. It is 1 of 3 probable Monier-type arch bridges in Bergen County (020020B, 020033D).

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a small stream in a post-World War II wooded residential neighborhood and next to the former location of Pulis's Mill. No buildings related to the mill are extant.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete arch bridge with concrete substructure was widened to both sides in 1960 with concrete slabs. Sidewalks with modern parapets and railings were also added. No plans to identify the steel reinforcement were located, but date, style, and design suggests that it employs the patented Monier reinforcing system represented in bridge numbers 020020A & 020033D. The span has lost its integrity, and 020020A, although similarly altered, has already been chosen as an eligible example.

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a small stream in a mixed commercial and residential area. Route 4 is accessible from the north approach. The surrounding neighborhood consists of apartment buildings built in the 1950s to 1960s. The setting is not distinguished.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The stringer bridge supported on a concrete substructure was built as a single span. In 1927 the span was widened with a flared superstructure and a concrete pier was added under the new longer stringers. Standard design balustrades were also added. Although plans were not located, county inspection records indicate the span was in place by 1916 and early maps indicate a crossing in 1902. One of over 65 stringer bridges in the county, the bridge is an undistinguished example of a common type.

DESIGNER/PATENT R. MCCLAVE, COUNTY ENGINEER **BUILDER** L. H. CARD

SETTING / CONTEXT The bridge carries a two-lane collector road over a river surrounded by wooded property owned by a water company. The bridge is adjacent to the site of the pre-1765 Old Bogert Grist Mill, abandoned in 1922 and demolished in 1932. The only above-ground remnant of the mill appears to be a dam-spillway upstream from the bridge. The existing bridge has no significant historical association with the mill site.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The continuous 2-span stringer bridge is supported by ashlar stone masonry abutments and a concrete pier. The haunched concrete fascias are not an uncommon method of making a steel stringer bridge appear as an arch bridge. The stone abutments probably predate the existing superstructure, but county records do not indicate the age or type of preexisting bridges. The stringer bridge is an example of a common type, and is not historically or technologically distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** ERIE RAILROAD

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a stream flowing through a picturesque ravine with wooded banks at the outskirts of the town center. The bridge is adjacent to the Undercliff railroad station which was established in 1908 by the Erie Railroad. According to one local history, the bridge was originally located in Narrowsburg, New York, and moved to Ho-Ho-Kus by the railroad as part of a plan to improve access to the station.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The Pratt truss bridge with pinned connections is supported on concrete abutments. The deck, sidewalks and railing have been replaced, but the truss is unaltered. Stylistically the bridge dates from c.1895, and was probably erected by the Erie Railroad as a rail carrying facility. It was re-erected as a highway bridge at the present site c.1908. It is the oldest of three surviving thru truss highway bridges in the county (020004B, 0204152), and is a significant example of the bridge type.

INFOR MATION

Bibliography:
County Engineers Office. Microfiche, Bridge Card 40-7.
1902 Map of Bergen County NJ, E. Robinson & Co.
Atlas of Bergen County, G.W. Bromley & Co., Vol. II, 1913. Plate 31.
Bergen County Division of Cultural and Historic Resources. Bergen County Historic Sites Survey, Township of Ho-Ho-Kus, 1981.

Physical Description: The 141'-span pin-connected Pratt through truss bridge is supported on concrete abutments cut into a ledge over a high ravine. The truss upper chord and end diagonals are built-up riveted back-to-back channels with a top cover plate and bottom lattice and verticals are back-to-back riveted channels with lattice. The end verticals and diagonals are pairs of rectangular-section bars and the lower chord members are pairs of rectangular-section eye-bars. Repairs were made to the floorbeam connections at the truss verticals at an unknown date as indicated by the bolted connections, however, the truss is unaltered. A concrete sidewalk lined by a metal fence is set to the fascia side of either truss. The earliest documentation of the bridge is plans dated 1921 for a deck replacement. Plans dated 1954 indicate the original timber sidewalks were replaced with concrete sidewalks and the sidewalk stringers were encased. In 1948 portions of the front of the abutments were rebuilt, and in 1963 and 1969 the abutments were repaired and waterproofing was added.

Historical and Technological Significance: Although the precise date of construction is not documented, early maps indicate that the span was erected sometime between 1902 and 1913, which is consistent with the style of the bridge. The bridge is the first crossing of the Hohokus Brook at this location and was built to access the adjacent Undercliff Train Station of the Erie Railroad, moved to its present location in 1908. The well-preserved span is the most complete example of its type in Bergen County . The bridge is historically significant because of its association with the railroad station and technologically significant because it is a virtually unaltered county example of a Pratt through truss span.

SUMMARY The 2-span deck girder bridge is supported on stone abutments and a concrete pier. The original metal railing is intact. One of over 28 pre-World War II girder bridges in the county, it is not historically distinguished or technologically innovative.

DESIGNER/PATENT R. MCCLAVE, COUNTY ENGINEER **BUILDER** A. H. ALFAST

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a shallow stream in a mixed commercial and residential area developed between the 1920s and the 1960s. The setting is not distinguished.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Although the span appears to have 2 paneled concrete parapets flanking each sidewalk, plans indicate the span is actually an encased Warren pony truss bridge supported on concrete abutments with cantilevered sidewalks bordered by paneled concrete parapets. The truss members are riveted I-sections and floorbeams are encased rolled sections. The truss encasement is paneled to match the parapets. A well-preserved example of a very uncommon bridge type, the span is technologically significant.

INFOR MATION

Bibliography:
Bergen County Engineers Office.(Plans).
"What County Engineer Did During 1918.", The Evening Record, Jan. 3, 1919.

Physical Description: The single span truss bridge supported on a concrete substructure is unusual because the Warren pony trusses are completely encased in concrete. Stringers and floor beams are also encased. Cantilevered sidewalks are bordered by paneled concrete parapets, and the encased trusses look like the parapets, being of the same height and detailed with matching panels. Plans indicate the truss is composed of riveted back to back channels forming I-sections. The floor beams are rolled sections and are connected to the trusses by riveted connections between the floor beam lower flange and the top flange of the lower chord.

Historical and Technological Significance: The encased Warren pony truss bridge was constructed in 1919 by A.H. Alfast, a local contractor, and was designed by the county. A shop drawing indicates the steel was provided by the Passaic Structural Steel Company, based in Paterson, NJ. There is no evidence suggesting the county engineering department, or any other county in the state, designed and constructed another bridge of this type, and it is the only known encased truss bridge in the state. The span is technologically distinguished because it is a very well-preserved example of what appears to be a unique design.

DESIGNER/PATENT BERLIN IRON BRIDGE CO. **BUILDER** BERLIN IRON BRIDGE CO.

SETTING / CONTEXT The bridge carries a single-lane, 2-way road over a river in a wooded setting. Farmland is to the north of the bridge. A historical marker notes that the bridge is named the Cleveland Bridge for the New Jersey-born president of the United States, Grover Cleveland.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1888 lenticular pony truss bridge supported on stone abutments was built by the Berlin Iron Bridge Company of East Berlin, Connecticut. The company's distinctive patented trusses were among the most popular highway bridge designs of the late 19th century. The bridge retains its integrity of design and was restored in 1983 with reinforcement of the top chords and verticals. A rare surviving example of its type, the bridge is both historically distinguished and technologically noteworthy.

INFOR MATION

Bibliography:
Bergen County Engineers Office. Bridge Card 3-17.
Bergen County Division of Cultural and Historic Affairs. Folio 25.

Physical Description: The lenticular wrought iron pony truss bridge with pinned connections is supported on sandstone ashlar abutments. The variable distance between top and bottom chord members of this 1888 truss forms a parabolic or lenticular truss shape. Top chord members are riveted built up channels with top cover plates and bottom lattice. Vertical members are 2 pairs of angles separated by lattice. The lower chord is composed of 2 rectangular section eye bars and diagonals are circular section bars. The riveted built up floor beams are tapered from a maximum depth at the center of the bridge and appear unaltered. Truss members have undergone some repairs in 1923 and 1983, but the structure retains its original 1888 construction appearance. Plates were welded to the top chord and vertical members, and the stringers and wood deck have been replaced.

Historical and Technological Significance: The iron lenticular pony truss bridge built in 1888 is a well-preserved example of an uncommon patented truss design built by a prominent bridge company during the peak of its operation at the end of the 19th century. The Berlin Iron Bridge Company of East Berlin, Connecticut, had been known as the Metallic Shingle Company prior to 1873 when its name was changed to the Corrugated Metal Company due to a change in products. Again in 1883 the name was changed to the Berlin Iron Bridge Company developing into a dominant structural steel fabricator credited for country-wide promotion of the lenticular bridge by the end of the century, a design that was patented by the company in 1878. In 1900 the company was acquired by The American Bridge Company, as were many bridge manufacturing interests at this time, and discontinued operation after 4 years. Noted by a Mahwah Historic Sites Committee marker as the Cleveland Bridge named for the former president of the United States, it replaced an 1840s wooden bridge that served the timber industry in the Ramapo Mountains and is one of 2 Ramapo River Bridges that survived the 1903 flood. This span is significant as one of the few extant iron bridges in the state with an unusual patented truss design as well as uncommon tapered floor beams.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1899 steel arch bridge employs a historically significant design patented by engineers Keepers and Thacher. Original plans indicate the bridge has flat steel bar ribs embedded in concrete. In 1958 the bridge was widened on both sides with concrete slab and parapet additions. Although visually altered, the arch portion of the bridge retains its integrity of design, and is 1 of only 2 Melan arch bridges in New Jersey attributable to Keepers and Thacher (1600017).

INFORMATION

Bibliography:
Bergen County Engineers Office. microfiche 70 B 9.
Bergen County Division of Cultural and Historic Affairs. Folio's 458 & 459. (Plans).
"Memoir of Edwin Thacher.", Transactions of the ASCE. Great American Bridges and Dams, by Donald C. Jackson. The preservation Press, Washington D.C., 1988.

Physical Description: The elliptical reinforced concrete arch bridge is supported on a concrete substructure. The plan indicates a 20' span at the spring line with a 2'-6" rise. The concrete arch is 18" thick at the abutments tapering to 6" thick at the crown and is reinforced with 8 pairs of flat bar ribs spaced at 3'-2 ½" on center and measuring 2" x 3/8". Concrete facings of the voussoirs and the spandrel walls were marked to represent masonry with the use of triangular strips 2" wide x 1" deep. In 1958 the bridge was widened to each side with a reinforced concrete slab supported on a concrete substructure.

Historical and Technological Significance: The reinforced elliptical arch bridge was constructed in 1899 by Keepers and Thacher Engineers, with an office in Paterson, NJ. The arch reinforcement is a patented design. Keepers and Thacher was a partnership between Mr. Edwin Thacher, Mr. W. H. Keepers and Mr. Wynkoop established in 1894 in Detroit, Michigan. Mr. Wynkoop dropped out of the partnership in 1895 and the partnership of Keepers and Thacher continued until it was dissolved on October 5, 1899. The firm constructed the concrete steel arch bridge over the Kansas River at Topeka, Kansas, at that time the largest bridge of its kind in the United States, and the Broadway St. Bridge over the Passaic River at Paterson, NJ.

Edwin Thacher was a prominent civil engineer having obtained patents for the "Thacher Cylindrical Slide-Rule"; "Thacher Steel Bridge Truss"; "System of Concrete Steel Arches" and "Thacher Combination Bridge Truss" among others. He held the positions of Chief Engineer for the Decatur Bridge and Construction Company of Decatur, Alabama, and the Keystone Bridge Company of Pittsburgh, Pennsylvania before opening his own Consulting Engineering Office in Louisville, Kentucky where he was responsible for the design of many truss spans including the 1891 Walnut Street Bridge crossing the Tennessee River in Chattanooga, and the 1892 Costilla Crossing Bridge across the Rio Grande in Colorado, an example of the Thacher truss patented in 1884 and designed to reduce the effect of temperature stresses on the truss members. In 1901 Thacher and William Mueser opened the Concrete Steel Engineering Company, headquartered in the Park Row Building in New York City. Thacher continued his work with this company until his retirement in 1912.

Although the span is short and has been widened, the arch bridge is noteworthy because it is an early example of the type with an uncommon reinforcement system and was constructed by a noted engineer.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The Pratt thru truss with counters bridge set on ashlar abutments has pinned connections. In 1968 the timber deck was replaced with a steel grid deck supported by channel beams and in 1985 one panel of the lower chord was supplemented with cables but alterations have not compromised the trusses integrity of design. The truss was built by prominent bridge engineers, and is a technologically significant example of a historically important and increasingly rare bridge type.

INFOR MATION

Bibliography:
Bergen County Engineers Office.
Bergen County Office of Cultural and Historic Affairs, Folio 307

Physical Description: The Pratt through truss with counters bridge supported on ashlar abutments with a span of 92' carries a 16' single-lane road. The pin connected truss has eye-bar lower chord and diagonal members, back-to-back channel section with top cover plate top chord and end inclined members, back-to-back channel with batten plates vertical members, and square section counters. The bridge carries the original metal railings. In 1954 the timber deck and wooden curbs were replaced. In 1968 the stringers were replaced, the back walls were rebuilt, a metal grate deck was placed, and the timber curbs were replaced with a metal channel section beam at the deck edge. In 1985 a crack was found in the south truss lower chord member at the west end panel. Cables with turnbuckles were placed as a repair measure, and the cracked lower chord member was removed. No original plans were located for the span, but the Bond between the county and the contractors was located.

Historical and Technological Significance: The Pratt through truss bridge was constructed in 1904 by Dean, Schwiers & Sutton Company of New York, a prominent bridge builder, to replace a span that was destroyed by the flood of 1903. Although the truss lower chord has repairs added at one panel, the remainder of the truss has not been modified. A long and early example of an uncommon bridge type, the span is distinguished.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The arch bridge set on stone abutments is composed of steel arch ribs supporting brick jack arches. In 1931 the bridge was widened to each side with concrete encased steel stringers set on concrete abutments. Concrete parapets and sidewalks were also added. The ribbed arch with brick jack arches bridge combines two technologically-significant turn-of-the-century bridge construction techniques, and is the only known highway bridge example of its type in New Jersey.

INFOR MATION

Bibliography:
Bergen County Division of Cultural and Historic Affairs. Folio 100. (Plans).

Physical Description: The single span steel arch bridge with brick jack arches is supported on sandstone ashlar abutments. The original plans indicate that the span consists of 8 inch deep rolled arched I beams with a 4'-6" rise at the crown and a 32'-0" span at the spring line and provided a 20'-0" roadway. The jack arches are a single layer of 4" brick topped with 4" min. plain concrete and span between the arched beams spaced at 4'-1" with 5 lines of 1" tie rods. The specifications required that the brick arch topped with concrete was to be covered with a coating of hot coal tar before placing the macadam to make the arch waterproof. According to county records, the northwest rubble masonry wingwall was rebuilt in 1924. To provide sidewalks, the span was widened to both sides with encased steel stringers on concrete abutments in 1931 as noted on the concrete balustrades. The original decorative metal railing set in blue stone coping 20" wide by 6" thick was removed when the bridge was widened.

Historical and Technological Significance: The 1897 bridge is an unusual design combining two bridge technologies; the brick jack arch and the rolled steel beam arch. The brick jack arch deck was a common design preference in Bergen County between the 1880s and about 1910. The builder, F. R. Long Engineers and Contractors, was a New York City firm that was a prolific bridge contractor in Bergen County, and it incorporated in New Jersey in 1899 moving its major operations to Hackensack. The span is technologically significant because it is an early well-preserved and well-documented example of a unique combination of bridge designs and is the only documented steel beam arch bridge in the county.

SUMMARY The steel stringer bridge with brick jack arches is supported on stone abutments. The bridge was widened to both sides with steel stringers with a concrete slab on concrete abutment extensions. The widening most likely took place in the 1930s as evidenced by the style of the concrete balustrades/parapets. A utility pipe added to the underside of the bridge damaged the brick jack arch. An altered example of a bridge type that is well represented in the county, the bridge is not distinguished.

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a small stream surrounded by commercial establishments built predominantly in the 1950s. The bridge is located just south of the New York State border and carries traffic on Livingston St. in NJ on to NY 303. Access to Livingston Street on the NY side is blocked by beam guide rail.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The slab bridge is supported on stone abutments from a previous span with concrete abutment extensions. The 1932 slab bridge reinforced with tied stringers replaced a 1906 stringer with brick jack arch bridge. The span is a short example of a common bridge type, and is neither technologically nor historically distinguished.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 12/07/89, Letter 6/30/95.

SUMMARY The 5-panel wrought-iron Pratt pony truss bridge has Phoenix column upper chord sections and is supported on stone abutments refaced with concrete. A Bailey bridge, placed in 1984, spans over the bridge to carry traffic, but is not an irreversible alteration. The bridge is 1 of fewer than 6 known surviving Phoenix column trusses in NJ built by Dean and Westbrook, highway bridge agents for the Phoenix Bridge Co. It is a technologically significant example of late-19th century construction.

DESIGNER/PATENT PHOENIX BRIDGE COMPANY **BUILDER** J. W. STAGG

SETTING / CONTEXT The bridge carries a 2-lane collector road and a sidewalk over the Hackensack River. The bridge is within the boundaries of a potential historic district identified by a SHPO finding. The district draws its significance from the well-preserved New Milford Pumping Station (1882-1906) located on an island south of the bridge which serves to connect the island with a 1960s residential area to the north. The bridge is listed as a potential contributing structure to the district.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible. Agreed Potential Historic District. Contributing.
CONSULT DOCUMENTS SHPO Finding 11/29/90, Letter 6/30/95.

SUMMARY The pin-connected wrought-iron Pratt pony truss bridge has upper chord and inclined end posts composed of patented Phoenix columns with cast-iron finials. In 1983 the trusses were relieved of live load by the addition of girders, but truss integrity was preserved. The bridge, already rated as contributing to a potential historic district, is individually eligible as a significant example of a late-19th century truss type. It is 1 of only 4 known Phoenix Column pony trusses in New Jersey.

INFOR MATION

Bibliography:
Bergen County Engineers Office. Bridge Card 25-5.
Bergen County Division of Cultural and Historic Affairs. Bergen County Historic Sites Survey, Town of Ho-ho-Kus, 1980-1981.
"The Rise And Fall of the Phoenix Column" by Alan Burnham, A.I.A, Architectural Record, April 1959.

Physical Description: The 76' long pin-connected Pratt pony truss bridge supported on ashlar abutments is composed of wrought iron Phoenix Column section upper chord and end inclined members. The lower chords and diagonals are pairs of eye-bars, and verticals are 2 pairs of angles separated by lacing. The 1892 trusses have finials on the top chords at each end. The original pipe railings are no longer in place, but the rail castings connected to the trusses are intact. In 1964 the stringers were replaced and topped with a metal deck. A cantilevered concrete sidewalk bordered by a chain-link-fence was added at the upstream side. In 1983 the trusses were relieved of live load by placing a girder bolted to the floor beams along the fascia-side of each truss. The trusses do not appear to have been significantly altered. The original plans for the bridge were not located, however, plans for the 1964 and 1983 alterations are available at the County Engineers Office.

Historical and Technological Significance: The Pratt pony truss bridge built in 1892 is technologically significant because it is a well-preserved example of a span built with patented Phoenix sections or columns. It is the more complete of 2 known Phoenix Column wrought iron truss spans in Bergen County. The Phoenix Column section was invented in 1862 by Samuel J. Reeves, the son of the founder of the Phoenix Iron Company of Phoenixville, Pennsylvania. It was an improvement over the widely used cast iron castings used as compression members in early metal truss bridges. Composed of four wrought channel-like sections joined at the flange by rivets, the Phoenix section proved as instrumental in the proliferation of metal truss bridges in the 1870s as any design detail of its day. By the early 1890s it was surpassed by the built-up box member of wrought iron or steel. The span is significant because it is a well-preserved example of this important although short-lived transitional technology.

SETTING / CONTEXT The bridge carries a 2-lane main street and sidewalks over a small stream just outside the town center and adjacent to Ridgewood High School (c.1916-1919).

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The steel arch bridge has concrete intrados, brick spandrel walls, stone voussoirs, and decorative metal railings with brick posts along most of its length. Although no plans were located, deterioration of the intrados exposes steel ribs of a Melan arch, and the bridge is identical in style and design to 020028D which dates to 1904. The steel-ribbed arch bridge is a well-preserved and richly-detailed example of a rare technologically and historically significant bridge type. The bridge is individually eligible for listing in the National Register of Historic Places under Criterion C.

INFOR MATION

Bibliography:
Bergen County Engineers Office.
Bergen County Office of Cultural and Historic Affairs.

Physical Description: The elliptical reinforced concrete deck arch bridge spans 58.4 feet at the spring line with a 9 foot rise, and carries a 30 foot road with 2 sidewalks. The spandrel walls are faced with buff brick and the voussoirs are of cut stone. Decorative metal railings are carried by the bridge and they span between pylons faced with buff brick to match the spandrel walls. Metal 3-rail pipe railings are carried on the approaches. About 30 feet of railing on the south side of the span is missing and was replaced with guide rail. Portions of the brick spandrel walls have been repaired. Spalls at the underside expose the bottom flanges of the melan type reinforcing system. No plans for the span were located.

Historical and Technological Significance: The elliptical deck arch bridge has unusual detailing that is not commonly found in New Jersey. The spandrel walls are of buff brick and the voussoirs are of cut stone. The railing pylons are of buff brick designed to match the spandrels. Two other extant deck arch spans in the county were constructed with similar detailing, 020028D and 020033D. They were built within the first 4 years of this century, dating this span to that period. These other spans have been widened and do not retain their design integrity. The melan arch bridge was first introduced in this country in the late 1800s, and the bridge is one of the earliest examples of the type in the county. The span is significant because it has uncommon detailing, and it is an early, long and well-preserved example of the melan concrete deck arch bridge.

SUMMARY The stringer and brick jack arch bridge supported on ashlar abutments has concrete repairs to one abutment. The original repaired railing is in place on one side of the bridge, and a beam guide rail flanks the other side. One of the few extant brick jack arch spans in the county that has no major alterations, it is historically and technologically significant as a well-preserved example of a common turn-of-the-century county bridge type.

INFOR MATION

Bibliography:
Bergen County Engineers Office. Bridge Card 59-10.
Bergen County Division of Cultural and Historic Affairs.

Physical Description: The single span stringer and brick jack arch bridge is supported on ashlar abutments. The bridge spans 36' and measures 21' out-to-out. The original decorative metal railing is at one side of the bridge only. Beam guide rail was placed at the other side. The north side of the west abutment was repaired with concrete. The remainder of the span appears unaltered. No plans were located.

Historical and Technological Significance: The stringer and brick jack arch bridge is an example of a bridge type that was commonly built in Bergen County from the early 1890s to around 1910. After 1910, concrete jack arch and then reinforced concrete slab replaced brick jack arch as the preferred deck type for new bridge construction. Although the span is not well-documented, early maps of the area indicate a span crossed this location in 1902, and the bridge card at the county engineers office indicates the span was in good condition in 1916. The span is a significant example of its type in the county because it is the longest stringer and brick jack arch span in the county, and it is the only example that does not have alterations to the brick jack arch superstructure.

CONSTRUCTION DT 1920 **ALTERATION DT** 1981 **SOURCE** NJDOT

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane collector road over a small stream in a residential area. The area was developed over many years with homes built from the early 1900s through the 1960s. The setting is not distinguished.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The slab bridge supported on stone abutments covered with mortar has a steel stringer at each fascia. In 1981 the original stringer superstructure was replaced but the fascia stringers remained in place. Concrete toe walls were placed in front of each abutment. Original railings have been replaced with beam guide rails. Because the bridge has been recently and significantly altered, it is neither historically nor technologically distinguished.

SETTING / CONTEXT The bridge carries 2 lanes of US 46 eastbound over 2 tiers of roadway including NJ 4 eastbound (0206187) and the I-95 ramps feeding into the approach to the George Washington Bridge. The original route designation of the bridge was NJ 1 and NJ 6 over NJ 4 and a county road, and was built in coordination with the Port Authority of New York's George Washington Bridge over the Hudson River project. The surrounding area is densely developed suburban residential and commercial.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible. Rt 46 Historic District. Eligible. Contributed.

CONSULT DOCUMENTS SHPO Finding 07/24/90 11/22/91, Letter 6/30/95, Opinion 02/21/97.

SUMMARY The 9-span bridge is an encased multi girder with concrete balustrades, abutments, and pier bents with encased steel pier caps. It is the top span of a technologically innovative three-tier traffic intersection in which all grade crossings have been eliminated in order to provide for the uninterrupted flow of traffic to the George Washington Bridge. The 1930 bridge is a technologically and historically significant example of NJ State Highway Department traffic engineering and design.

INFOR MATION

Bibliography:
NJDOT.
Transactions of the American Society of Civil Engineers, vol. 97, 1933. Paper No. 1825, "George Washington Bridge: Approaches and Highway Connections" by J.C. Evans, Esq.

Physical Description: The 9-span 476' long encased multi-girder bridge supported on a concrete substructure was built on a horizontal curve. The 60' out-to-out width bridge carries 2 eastbound lanes of a highway and variable width grass and concrete sidewalks flanked by standard design concrete balustrades. Bridge 0206187 spans underneath the bridge.

Historical and Technological Significance: The encased multi-girder bridge was constructed by the New Jersey State Highway Department Bridge Division in 1930 to carry the eastbound lanes of US 1&9 & 46 over span 0206187 which carried the eastbound lanes of NJ 4 over a local access road to the city of Fort Lee. In the 1960's, US 95 was constructed and the Lower Level Expansion of the George Washington Bridge was completed. At that time the lower level access road became an eastbound ramp of US 95. The bridge is part of a three-level grade crossing constructed to connect state highways with the New Jersey approach to the George Washington Bridge. This three-level road intersection was constructed in coordination with the Port of New York Authority George Washington Bridge project. Although the bridge is a common type, the span is significant because it is part of an innovative three-tier structure associated with the George Washington Bridge approach construction.

SETTING / CONTEXT The bridge carries a 4-lane barrier-divided arterial road with sidewalks over a major river, a 4-lane divided arterial road and a 2-lane collector road. The setting is predominantly post-World War II commercial. Apartment buildings in the area date to the 1960s.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span reinforced concrete open spandrel arch bridge has 4 steel stringer approach spans. In 1988 the bridge deck, sidewalks and parapets were replaced but original obelisk concrete lamp posts were retained. The bridge is 1 of over 10 multi-span open spandrel arches designed by the State in the 1920s and early 1930s. Superstructure alterations have substantially reduced the bridge's integrity, and more distinguished examples of the bridge type exist within NJ (1203150, 1607163).

 # SPANS 1 **LENGTH** 58 ft **WIDTH** 83 ft

CONSTRUCTION DT 1931 **ALTERATION DT** **SOURCE** PLANS

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries a 4-lane barrier-divided highway and sidewalks over vacant land set aside in 1931 for a proposed extension to Lafayette Avenue which was never built. The overpass is located at the beginning of the greenbelt area along NJ 4 that provides a natural buffer between the highway and the surrounding community. A golf course is located to the south of the bridge, and to the north light industrial buildings (c.1940-70).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-preserved encased stringer bridge supported on concrete abutments with panelled pilasters has a balustrade of standard design. The span is an example of the nicely detailed overpasses designed by the State Highway Department in the pre-WWII era. One of over 65 stringer bridges in the county built prior to 1946, the span is a common bridge type that is neither technologically innovative nor historically distinguished.

SETTING / CONTEXT The bridge carries 2 eastbound lanes of NJ 4 over a ramp of I-95 and under a bridge carrying 2 eastbound lanes of US 46 (0202160). The original route designation of the bridge was NJ 4 eastbound over a county road and under NJ 1 and 6. It was built in coordination with the Port Authority of New York's George Washington Bridge over the Hudson River project. The surrounding area is densely developed suburban commercial and residential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Rt 46 Historic District. Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/21/97.

SUMMARY The heavily-skewed, single-span bridge is an encased thru girder with scored concrete abutments and cantilevered sidewalks with metal railings. It is the middle span of a technologically innovative 3-tier traffic intersection in which all grade crossings have been eliminated in order to provide for the uninterrupted flow of traffic to the GW Bridge. The 1930 bridge is part of a structure which is a technologically and historically significant example of NJ State Highway Department engineering.

INFOR MATION

Bibliography:

NJDOT.

Transactions of the American Society of Civil Engineers, vol. 97, 1933. Paper No. 1825, "George Washington Bridge: Approaches and Highway Connections" by J.C. Evans, Esq.

Physical Description: The skewed encased thru girder bridge spans 81' and carries a 36' wide eastbound highway. Cantilevered sidewalks are flanked by metal railings with concrete posts. Railing posts are paneled with bush-hammered finish. The concrete abutments have horizontal linear scoring. Bridge 0202160 spans over the bridge. The bridge appears to have no alterations.

Historical and Technological Significance: The encased thru girder span was constructed by the New Jersey State Highway Department Bridge Division in 1930 to carry the eastbound lanes of NJ 4 over a local access road to the city of Fort Lee. In the 1960s, US 95 was constructed and the Lower Level Expansion of the George Washington Bridge was completed. At that time the road under the bridge became an eastbound ramp for US 95. The bridge is part of a three-level grade crossing constructed to connect state highways with the New Jersey approach to the George Washington Bridge. Bridge 0202160 spans above the bridge and carries the eastbound lanes of US 1 & 9 & 46. This three-level road intersection was constructed in coordination with the Port of New York Authority George Washington Bridge project. Although the bridge is a common type, the span is significant because it is part of an innovative three-tier structure associated with the George Washington Bridge approach construction.

CONSULT STATUS Not Individually Eligible. Potential trolley line Historic District, May contribute.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY 0207151

National Register Consultation Status: Not Individually Eligible; May be a contributing element of a potential trolley line historic district

The 3-span slab bridge supported on concrete abutments and concrete pier bents was constructed on a large skew. The sidewalks are bounded by plain parapets and a utility pipe is hung from the underside of the slab. The span is a representative example of a common bridge type. The Public Service Railroad [P.S.E. & G. trolley] right of way may have historic significance and be eligible for listing in the National Register of Historic Places as a linear historic district. Future evaluation efforts should consider the bridge in the context of the potential district.

SETTING / CONTEXT The span carries a 2-lane city street over a major river between the towns of Belleville and North Arlington. The area is a mix of post-World War II commercial buildings and 1920s residential. NJ Route 21 borders the river. A bridge has spanned the Passaic at this historically important crossing since 1790. The bridge is located at the junction of the boundaries of Bergen, Essex, and Hudson Counties.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The heel trunnion single-leaf bascule bridge with a riveted Warren thru truss main span and riveted Warren pony truss approach spans is supported on concrete substructure. The original decorative metal railing is extant. The open grid metal deck on the main span was added in 1972, and the operators' house was rebuilt in 1990. The span is well-preserved and technologically significant example of an uncommon bascule bridge type constructed by a prominent bridge company. It is individually eligible for listing in the National Register of Historic Places under Criterion C.

INFOR MATION

Bibliography:
NJDOT (Plans), personal interview with bridge tender, Movable and Long-Span Steel Bridges, by Hoole and Kinne, McGraw Hill Book Co., Inc., 1923.

Physical Description: The Strauss heel trunnion single-leaf bascule bridge supported on a concrete substructure is composed of a riveted Warren through truss main span of 116' and three 60' approach spans to the east side of the main span. The 2 easternmost approach spans are riveted Warren pony trusses and the span adjacent to the bascule span was replaced with a multi-girder span in the 1980's. The most prominent feature of the bridge is the span's massive overhead steel tower structure that includes the supporting truss for the overhead concrete counterweight, and the mechanical pivots, connecting struts, and the operating struts. These exposed operating mechanisms as well as the trusses and the decorative metal railings appear to be unaltered. The floor beams appear to be original but the stringers and the metal grate deck were replaced in 1972. In 1990 the operators house, cantilevered off the south side of the bascule span at the location of the tower structure, collapsed and fell into the river. It was replaced with an aluminum building. The gate keepers house is located on the north side of the bridge on the approach span that is adjacent to the bascule span. The original house was located on the north east approach but was moved onto the span at an unknown date due to a property dispute.

Historical and Technological Significance: The Strauss heel trunnion bascule bridge, constructed in 1914, is a well-preserved example of an uncommon bridge type in New Jersey, and it is technologically significant because it is a patented design by The Strauss Bascule Bridge Company of Chicago, a prominent bridge company that held several patents for bascule bridge designs. The heel trunnion is a variation on the articulated parallel-moving counterweight design developed by Joseph B. Strauss in 1905. The distinctive feature of this design is the above deck steel structure composed of the operating mechanisms for the bascule span and their support structures, and the overhead supporting truss for the counterweight. The span pivots about the main trunnion which is located at the base of the truss end inclined member. The operation is initiated by a motorized pinion that engages the rack on the operating strut. The operating strut is pin-connected to the top of the truss inclined end member. This pin, one of 4 pivot points on the operating structure, translates with the strut, rotating the span as it translates. The 4 pivot points are connected by struts that form a parallelogram. 2 of the pivots translate together and the 2 trunnions remain stationary so that, when in operation, the parallelogram closes and the counterweight, which pivots about the counterweight trunnion through its supporting truss members, moves downward. This complex structural network maintains a condition of constant balance during operation of the bascule. An illustrated explanation of the bascule operation is attached.
Known as the Rutgers bridge named for Anthony Rutgers who owned the first bridge crossing at this location, a wooden toll bridge constructed in 1790, the history of crossings at this location is outlined by a Belleville Historical Society Marker at the southwest approach. The first timber bridge was destroyed by flood in 1841. A new span was built in 1843 that was sold to the three counties in 1851 and became a free bridge. An iron bridge replaced this span in 1879 and remained until the present bridge was constructed.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER** GEORGE M. BREWSTER & SON

SETTING / CONTEXT The 5-span, 4-lane bridge with sidewalks spans the depressed multi-lane approach to the George Washington Bridge (GWB). The overpass and three other overpasses to the east (3800004,5,9) were built in 1930-1 in coordination with the GWB in order to carry existing traffic patterns over the approach. The approach itself does not constitute a historic corridor because it is not technologically innovative and has lost its integrity of setting with numerous modern intrusions including high rises.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Historic District Status Unresolved.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased steel stringer bridge with metal railings and concrete abutments and piers was built in 1930 as a three span overpass. In 1964, as part of the GWB lower level expansion, the 2nd and 4th spans from the north were added, and a steel stringer span (0202161) was added to the south. The altered overpass is not technologically or historically significant because it is an example of a typical NJ State Hwy. Dept. solution to separating traffic in a congested area.

SETTING / CONTEXT The bridge carries NJ 17 (formerly NJ 2), a 4-lane barrier-divided highway over the main line of the New York, Susquehanna and Western Railroad. The bridge is bordered by a covered landfill to the east and 1980s apartments to the west. The railroad right-of-way was developed in the 1870s by the New York, Susquehanna, and Western Railroad, which was purchased by the Erie Railroad in 1898.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span encased stringer bridge supported on concrete abutments and open concrete pier bents has a new concrete parapet with a chain-link fence and a new sidewalk placed along the west side. The bridge is a representative example of a common 1920s and 1930s NJ State Highway Department railroad overpass design, and is not historically or technologically distinguished. A similar bridge (0214157) carries NJ 17 over a nearby spur of the same rail line.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries US 46, a 4-lane divided highway with modern median barriers, over a 2-lane collector road in a residential neighborhood dating from the 1920s to the 1950s. The land bordering US 46 is undeveloped and wooded. US 46 was designated as NJ 6 prior to a 1953 route renumbering and was constructed as a result of a 1927 act expanding the system of state highways in NJ.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/21/97.

SUMMARY The encased stringer bridge supported on concrete abutments has standard design concrete balustrades. Panelled concrete pilasters stand at each abutment corner. The span is an example of the well-detailed State Highway Department overpasses produced during the period of expansion in the 1920s and 1930s. One of 15 similar bridges along US 46 and one of over 65 stringer bridges in the county, the span is a common type and is neither technologically innovative nor historically noteworthy.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Opinion 02/21/97, Letter 03/12/01.

SUMMARY The double-leaf deck-girder trunnion bascule bridge has 16 deck girder with encased floorbeams approach spans. The operators' houses appear unaltered and major repairs have been limited to deck reconstruction and the bascule locks (1968-73). Noted bridge engineers Waddell and Hardesty designed the 185' bascule span for the NJ State Highway Department. It is a technologically distinguished, historically significant, and well-preserved example of an increasingly rare bridge type, which is eligible for listing in the National Register of Historic Places under Criterion C.

INFOR MATION

Bibliography:
NJDOT (Plans)
New Jersey Office of Historic Preservation Historic Sites Inventory # 0250-1, 0230-4
Dictionary of American Biography, volume XI, Charles Scribner's Sons, New York, 1958.

Physical Description: The 1549' long double leaf bascule deck girder bridge supported on a concrete substructure has 16 approach spans composed of deck girders with encased floor beams and stringers. According to plans, the bascule span measures 185' center to center of trunnions and piers, and the variable depth bascule girders are spaced 53' on center. The road measures 50' between curbs. Two 8' concrete sidewalks are bounded by metal railing on the bascule span and concrete balustrades on the approach spans. Four octagonal concrete towers with pyramid roofs and decorative light standards are located at the corners of the bascule span. The tower at the northwest corner of the span is taller than the others and houses the operating mechanisms. The northeast and southwest towers are the gate tender's houses, and the tower at the southeast is a storage house. Alterations to the bridge are limited to an approach span deck reconstruction in 1973, redecking of the bascule span in 1969, and reconstruction of the center lock in 1968.

Historical and Technological Significance: The double leaf bascule deck girder bridge was constructed by Waddell and Hardesty Consulting Engineers for the New Jersey State Highway Department in 1934. The partnership of John Waddell and Shortridge Hardesty, formed in 1927, was noted for their innovative bridge designs. They were responsible for the Mississippi Highway Bridge, a 3,720-foot cantilever at Cairo, Ill., across the Mississippi (1929); the Anthony Wayne High Level Bridge at Toledo, Ohio, a suspension span across the Maumee River (1931); and they were one of the consulting engineers on several major bridges in New York City, including the Outerbridge Crossing and the Goethals Bridge in 1928, and the Marine Parkway Bridge across Rockaway Inlet, with a 540-foot lift span, in 1936-37. John Waddell, a native of Canada and one of the United States best-known civil engineers, opened his first consulting engineering office in Kansas City Mo. after returning from Japan where he held the position of professor of civil engineering at the Imperial University of Tokyo from 1882 to 1886. In the early 1890s Waddell independently invented and successfully introduced the large-scale high-clearance vertical-lift bridge in the United States which became widely used, especially for railroad crossings over waterways. Waddell published many papers and books on engineering including The Designing of Ordinary Iron Highway Bridges (1884), Bridge Engineering (2 vols., 1916), and Economics of Bridgework (1921).

The bridge spans the Hackensack River, an important navigable waterway in northern New Jersey. In early NJ history, the town of Little Ferry was an important termination of Indian trails and a river crossing. When the Europeans arrived in the area they established a ferry crossing here which gave the area its name. The first bridge in the town across the Hackensack was erected in 1812. The current bridge replaced a small metal truss bridge located at a site further to the south.

The bridge was constructed to carry State Highway Route 6 as part of the expansion of the state highway system in the 1920s and 1930s. The bascule bridge was preferred over the swing spans because they could be constructed with longer span lengths. The span is one of only 2 double leaf bascule spans constructed in the 1930s in Bergen County. 0222150, constructed to carry the same state highway over Overpeck Creek in Ridgefield Park Village, has been altered and no longer functions as a bascule bridge. The span is technologically significant as an example of an uncommon type, and it is the only remaining operational span of its type in the county. The well-preserved span is historically significant because it was designed by a prominent civil engineer.

Boundary Description and Justification: The bridge is individually eligible, in and of itself, including superstructure, operators' houses and machinery, substructure, and right-of-way over the river.

SETTING / CONTEXT The bridge carries US 46, a 7-lane divided highway with sidewalks, over a wide river in a commercial area dating from the early 1900s to the 1980s. US 46 was designated NJ 6 prior to a 1953 route renumbering and was constructed as a result of a 1927 act expanding the network of state highways in NJ.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/21/97.

SUMMARY In 1928 the bridge was built as a double leaf deck girder bascule bridge on concrete substructure. In 1951 the bridge was widened with steel stringers on the downstream side indicating that by that time the bascule was inoperable and the operators' houses and mechanism had been removed and the span fixed in place. The span is significantly altered and has lost its design integrity and purpose. An intact and distinguished example of the double leaf bascule bridge type is 0221155.

SETTING / CONTEXT The bridge carries a one lane 2-directional town road over Conrail tracks in a residential area developed from the 1920s to the 1940s. The bridge is located at the outskirts of the town center. The railroad right-of-way was developed in the 1880s by the New York West Shore and Buffalo Railway Company. In 1885 the railroad agreed to build the bridge across the right-of-way to connect farmland on either side of the track.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span timber truss bridge supported on stone abutments and timber pier bents has a cantilevered sidewalk added in 1967. In 1985 the center span was replaced with a timber glulam superstructure. Property deeds indicate the span was likely built in the 1880s, and plans confirm the bridge was in place by 1903. The truss bridge was rebuilt in kind in 1946. The only known surviving timber truss in the survey, the bridge is associated with the construction of the railroad and is noteworthy.

INFOR MATION

Bibliography:
Bergen County Division of Cultural and Historic Affairs. file Haworth - Ivy Avenue Bridge. Haworth Historic Sites Survey, 1983.
files of and personal interview with Mrs. M. Cooper, Haworth Historical Society.

Physical Description: The 3 span timber bridge supported on ashlar abutments and timber bents spans over Conrail tracks in a deep ravine. The entire superstructure was rebuilt in kind in 1946 according to Conrail records. Originally a 3-span timber pony truss bridge, in 1985 the center trusses were removed and replaced with a glulam deck superstructure topped with asphalt. The remaining truss spans have timber floor beams hung from the top chord members with steel bars and anchor plates, and timber stringers and deck planks. A plan dated 1903 indicates the steel bar hangers were not in place and were added at a later unknown date. A cantilever sidewalk was added in 1967, and it is bordered by a chain-link-fence.

Historical and Technological Significance: The timber pony truss bridge was likely originally built by the New York West Shore and Buffalo Railway Company in the 1880s. The railroad through Haworth began as a single track constructed in the 1870s by the Jersey City and Albany Railroad, which failed shortly after opening the line. The New York West Shore and Buffalo Railway Company built a second track and began operations in the 1880s. The Phyfe's, who owned farmland along the track in Haworth, donated land for the construction of the additional track. In exchange, the railroad agreed to build at least one bridge spanning the railroad to connect the Phyfe's property on either side of the tracks for their personal use as a crossing for cattle and farm equipment. An 1888 map of Haworth shows 2 bridges spanning the tracks in the vicinity of the Phyfe's property, including a span at Ivy Avenue located at the southernmost border of the Phyfe's property. The earliest plan located, dated 1903, was prepared by the New York City and Hudson River Railroad, who took over operations on this line. The 1903 plan does not appear to be construction plans but rather documentation of the existing bridge. The span is technologically distinguished as one of the few remaining early timber truss bridges in the state, and the bridge is historically of note because it is associated with the construction of the railroad.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-span bridge has a thru girder main span and deck girder approach spans supported on concrete abutments and mixed concrete piers and a steel pier bent. A temporary timber support was placed under the south girder of one approach span. The original metal railing is intact along most of the bridge. An example of a common bridge type and one of over 23 pre-WW II thru girder bridges in the county, the bridge is neither technologically innovative nor historically distinguished.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane residential city street with sidewalks over a railroad. The buildings in the neighborhood are predominantly post-World War II vintage multi-level apartments. The New York, Susquehanna, and Western Railroad developed the right-of-way in the early 1870s. In 1898 the Erie Railroad acquired the line.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The concrete arch bridge has a concrete substructure and balustrades with decorative balusters. The railings have been rebuilt in places, and the light standards removed. The bridge is similar in style to 020023C which also spans the railroad in the vicinity. The bridge is a relatively early example of reinforced concrete deck technology and is longer than most other structures of this type. The architectonic character is a manifestation of the City Beautiful Movement, which resulted in many highly decorated civic structures in the area. It is an unusual choice of structure type for a railroad overpass. It is individually eligible for listing in the National Register of Historic Places under Criterion C.

INFOR MATION

Bibliography:
NJDOT Bridge Plan File: Bergen. Condit, Carl. American Building Art 19th Century. 1960.

Physical Description: The 79'-long reinforced concrete elliptical-shaped deck arch bridge has incised panels in the spandrel walls. The custom balustrade has square end posts with incised concentric square decoration and balusters detailed like stacked rusticated block. Some of the original balusters are lost and have been replaced with concrete block. The span is well proportioned and has sidewalks flanking the roadway.

Historical and Technological Significance: The handsome deck arch bridge built in 1906 by the Erie Railroad over its depressed right-of-way is a relatively early example of a longer reinforced concrete arch bridge and is thus a good representative of the bridge type that became very popular in northern New Jersey during the decades before World Was I. No plans for the bridge were located, but it was built over the right of way initially developed in the 1870s by the New York Western, and Susquehanna Railroad that was acquired by the Erie Railroad in 1898. Because of its urban setting, the bridge was aesthetically detailed in conformance with the prevailing City Beautiful concepts of making public works structures interesting and beautiful as well as functional (criterion C). The area surrounding the bridge in Hackensack has been redeveloped with predominantly post-World War II apartment houses.

The reinforced concrete deck arch bridge was first used in this country in the late 1880s, but it was not until the late 1890s that the bridge type gained in popularity. By 1905 it was ubiquitous for short (less than 60') spans. This bridge is significant for its size and for its fine custom detailing evident in the railings. The bridge exploits the plastic qualities of concrete. Concrete was favored by some railroads, like the DL&W, but concrete overpasses are not nearly as common in New Jersey as built-up girder bridges on concrete abutments.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is thus limited to the substructure and the superstructure. The neighborhood surrounding the structure has been redeveloped since World War II, so it is not contributing.

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-leaf bascule bridge is a well-preserved example of a patented Strauss articulated underneath counterweight. It is also important because it is a chain-driven operating mechanism powered by a gasoline engine, and it may well be the only example of such an operating arrangement in the state. The approach spans are wood stringers supported on pile bents. The bridge is remarkably complete and technologically significant.

INFOR MATION

Bibliography:

NJDOT. Bridge File #0302150. Engineering News-Record. Vol. 120 (May 129, 1938). p. 702. "J.B. Strauss Dies at Los Angles."

Physical Description: The 19-span bridge is composed of 18 short timber stringer supported on pile bents approach spans and a single-leaf deck girder moveable span with an articulated underneath counterweight. The moveable span, with a modern steel grid deck, was designed by the Strauss Bascule Bridge Company of Chicago, and it is a patented design. The moveable span pivots on two trunnions which bear on built-up trunnion towers or columns on a concrete pier. The articulated concrete counterweight moves on linkage and is located under the tail of the moveable span. The manual lattice crash gates and manual locks operated by a hand lever are both original to the span. There are no electrical toe locks. A frame, gable-roofed operators shanty is located on the north end of the downstream side of the moveable span while the operators house is at the south end of the same side. Both buildings are well preserved.

As significant as the moveable span is the operating machinery. The lifting machinery is chain rather than gear driven, and the power source is a Hercules-manufactured gasoline engine. The chain drive may have been selected because of the distance between the engine (power source) and line shafts. Such an arrangement would protect the engine from water damage. Three sets of chains and sprockets are used in the operation of the span. The first speed reduction chain services the reversing gear control to raise and lower the bridge. The second speed reduction chain connects the reversing unit output shaft to a drive sprocket on the first line shaft located under the bridge. A third reduction chain and sprocket powers the secondary transverse shaft with the pinion that engages the segmental rack which raises and lowers the bridge. The operating mechanism appears to be original and has not been modified. Work to the other elements of the span is best characterized as maintenance rather than modification or alteration. With the exception to the new concrete piers for the first line shaft, the bridge appears to survive as built.

Although the wood stringer approach spans have been repaired and rebuilt, the work has been in kind, and it survives as a good example of timber stringer bridge technology.

Historical and Technological Significance: The 1925 bridge that carries US 9 over the Bass River is not only a well-preserved example of a patented Strauss articulated underneath counterweight moveable span bridge, it is also possibly the only chain-driven, gasoline-engine powered moveable bridge in the state. The technological significance of this uncommon mechanical arrangement is matched by the nearly complete state of preservation that the bridge enjoys. It survives, complete with operators shanty and machinery house, as built in 1925, and ranks as one of the most important moveable span bridges in the state.

J.B. Strauss (1870-1938) patented his articulated counterweight bridge in 1905 (patent granted in 1911). The design went on to become one of the most popular in the nation prior to World War II, and it was his best-known design. The underneath counterweight, however, is not as common as the overhead position like that used at Green Bank over the Mullica River and at Federal Street in Camden. The parallelogram-linked counterweight that moves parallel to itself when the bridge is in operation facilitated a lighter counterweight and eliminated the need for a deep counterweight pit.

Chain-driven moveable bridges are not common, although the arrangement is appropriate when the power source and drive shafts are not closely spaced or the bridge is located in an area that is prone to high water that might inundate the engine or motor. The use of chains and sprockets eliminates the need for several sets of reduction gears. No other chain-driven bridge has been identified in New Jersey, but two others are known to survive; the Quinnipiac River at New Haven Connecticut and the ca. 1900 NYNH&H RR bridge over the Sakonnet River at Tiverton, Rhode Island. Both of those bridges, however, are powered by electric motors. This is also the only bridge documented to date that is powered by a gasoline engine. It appears that the engine is original to the bridge.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete encased steel stringer rests on reinforced concrete abutments and wingwalls. The original bridge doubled in size with an addition made on the western side in 1963. A typical concrete balustrade is on the older section of bridge, while a concrete parapet adorns the newer part. A concrete guiderail runs down the center of the road separating the north-south traffic. The bridge is a common type, and it has been altered too much to have historical significance.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries two active lanes of southbound traffic and an abandoned 2-lane portion of US 130 over a tidal creek in a twentieth-century commercial area of Burlington. US 130 is a divided highway at this point, with about 50 yards between north and southbound traffic. Northbound traffic is carried on a separate span (0317150) built in 1963. The realignment of northbound traffic eliminated the need for the upstream portion of the older bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span bridge on a concrete substructure was built in two sections. The original span is an encased thru girder with floor beams and a cantilevered sidewalk on upstream side. It was widened in 1935 with a 2-lane encased stringer span finished with a concrete parapet at the sidewalk. The thru girder portion has been abandoned, and is now covered with dirt and grass. Both sections of the bridge are representative examples of their bridge types, and the span is not distinguished.

SETTING / CONTEXT The bridge carries two lanes on one-directional traffic over the abandoned and overgrown right-of-way of the Kinkora Branch RR of the PA RR. The right-of-way is now used for high voltage lines carried on towers. The bridge is next to but does not share a substructure with 0317157 which carries southbound traffic. The setting is wooded with sparse 20th century development. The railroad, named after the original name of the area, serviced Roebling.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span bridge is composed of deck girder approaches and a built-up thru girder main span. The concrete substructure has stub abutments and pier bents. All floor beams are encased. The original pipe railing survives only at the easterly girder. The approach concrete balustrades match those used on the parallel span added in 1936. The top of the thru girder now serves as a mid-roadway barrier. The bridge has lost integrity of design and setting, and it is not historically noteworthy.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased thru girder with floor beams bridge is supported on a concrete substructure. The cantilevered sidewalk is enclosed by a metal railing with concrete posts. The thru girder was a frequent bridge type utilized by the State Highway Department during its ambitious early-1920s program to develop the 15 original state highways in the state. The route, designated as Rt. 2 in 1917, ran from Trenton to Camden. The bridge is a common type and is not technologically or historically noteworthy.

SETTING / CONTEXT The bridge carries a 2-lane city street and sidewalks over 1 active rail line in a residential section of the Bordentown Historic District. The rail line passes through the town on a depressed right-of-way that is lined with a retaining wall of either concrete or ashlar masonry. The wall has been repaired many times, most recently in 1991. Three city streets cross the railroad in a three block area. The line is the original route of the Camden & Amboy line and dates to 1831.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Camden & Amboy Railroad Main Line Historic District, Eligible. Listed. Bordentown Historic District. 06/14/1982. Contributing / Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 1998.

SUMMARY The encased stringer span is supported on concrete bearings that are rebuilt sections of the early ashlar retaining wall that protects the depressed roadbed. The iron fence railing used at the sidewalks is the same used to enclose the roadbed between Farnsworth and Prince streets. Although the bridge is located within the boundaries of the Bordentown HD, and it crosses the earliest rail line in the state, it is not an early span, and it is outside the district's period of significance.

CONSTRUCTION DT 1831ca **ALTERATION DT** **SOURCE** LOCAL HISTORY

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The arch carries the main street of Bordentown, two sidewalks, and a small green space over the single track of the former Camden & Amboy line, the earliest rail line in New Jersey. The C & A developed the line from the canal terminus in Bordentown to New Brunswick in the early 1830s. The town grew in response to the railroad and canal, and it retains its 19th century character. Most of the small town is listed as a district in the National Register.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Camden & Amboy Railroad Main Line Historic District, Eligible. Listed. Bordentown Historic District. 06/14/1982. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 1998.

SUMMARY The nearly 100'-long rubble-coursed stone arch bridge with gauged ring stones appears to be an original feature of the ca. 1831 rail line. The west spandrel wall and intrados have been parged, but most of the coating has spalled. No original railings survive, but the arch is remarkably complete making it a large and well-preserved example of its type. It is the oldest bridge in the county, and it contributes to the historic character of the Bordentown Historic District.

INFOR MATION

Bibliography:
ONJH. National Register File; Burlington County; Bordentown Historic District, 1982. Bordentown Historical Society. Bordentown 1682-1976. 1976.

Physical Description: The 22'-long, 97'-wide rubble-coursed stone arch bridge with gauged ring stones is finished with rubble-coursed spandrel walls. The one on the west side has been parged. At some point the intrados of the arch was gunited, but most of the cementous coating has spalled. The arch span carries the main street of Bordentown and site of a former passenger station over the depressed single-track right-of-way of the railroad, and the roadbed is lined with retaining walls of both ashlar and concrete. The retaining wall on the east side of the arch was buttressed with concrete in 1991.

Historical and Technological Significance: The well-preserved stone arch bridge is individually distinguished as being an early regional example of its type, ranking as the oldest documented bridge in Burlington County. But it is its historical associations that make it an important landmark and a contributing resource in the Bordentown Historic District (Criterion A). The span was built ca. 1831 by the Camden & Amboy Railroad as part of its development of the first railroad in the state. Bordentown, located on the terminus of both the C & A Railroad and the Delaware & Raritan Canal, grew and prospered servicing the transportation industry. The town survives as a well-preserved 18th and 19th-century community whose development was virtually complete by the first world war. Almost the entire mile-square city is listed in the National Register as a district because of its significance it architecture and transportation. The bridge is an early and a historically important structure that contributes to the historic character of the district, and it is one of the few extant tangible records of the early days of railroading in the city that owes so much of its development and appearance to the "iron horse."

Boundary Description and Justification: The bridge is wholly within a National Register-listed historic district that encompasses most of the corporate limits of Bordentown City. It and the surrounding structures are contributing resources. For a detailed district boundary delineation, refer to the National Register files at ONJH.

SETTING / CONTEXT The narrow two-lane bridge carries traffic over the Rancocas Creek in a wooded, twentieth-century residential area on the edge of Willingboro, a post-World War II Levittown suburb. The bridge is in the village of Centerton, a town created in 1832 when an iron bridge spanned the creek at this site for the first time. The historic village of Rancocas lies about 1-1/2 miles north of the bridge. Historically, Centerton was a center for phosphorus for fertilizer and industry.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The riveted Warren pony truss bridge has three fixed approach spans and one main center bearing swing span, originally built by the NJ Bridge Co. of Manasquan, NJ. Rehabilitation's in 1954 and 1985 resulted in replacing elements of the floor system and some in-kind replacement of the manual drive mechanism. But, overall, the span is an early and well-preserved example of a center-bearing swing span. It is also the work of a New Jersey bridge fabricator, which adds to its historical value. The bridge is individually eligible for listing in the National Register of Historic Places under Criteria A and C.

INFOR MATION

Bibliography:
Burlington County Engineer's Office. Bridge File C4.4. "Manasquan, New Jersey." Compiled by the Townfolk for the Diamond Jubilee under the Sponsorship of the Manasquan Chamber of Commerce. 1962. Woodward, E.M. History of Burlington County New Jersey. 1883.

Physical Description: The well-preserved 4-span bridge is composed of light, rivet-connected Warren with vertical pony trusses, 3 of which are fixed spans, and one is a manually operated center-bearing swing span supported on a concrete and stone substructure. All piers except the swing span pier have been augmented by modern steel pier bents. The trusses are designed for secondary stresses, and the top chord and inclined end posts are composed of channels with cover plate. The diagonals and verticals are laced angles while the bottom chords are channels connected by battens. The steel is Phoenix produced. The swing span is supported in the center by a transverse girders with balance wheels that guide the span in opening. A capstan is used to engage the rack and pinion gearing that moves the span. The bridge was never anything but manually operated.

There are no significant alterations to the bridge. In 1985 the approach span decks and stringers were replaced, and there were some repairs to the floor beams. The center bearing was also replaced in kind.

Historical and Technological Significance: The manually operated center bearing Warren with verticals pony truss swing span bridge built in 1903 was fabricated by the new Jersey Bridge Company of Manasquan, New Jersey (Criterion C). In addition to being a well-preserved example of a swing span bridge, it is one of less than six documented bridges by the state fabricator, and that increases the historic significance of the span. Unfortunately, no original plans of the bridge are preserved in the county engineer's office.

The New Jersey Bridge Company was founded at Manasquan in 1890, and it was active until 1907 when financial reversals forced the company to close. It was established by Mr. Wyckoop and Mr. Braly from Canton, Ohio. In its heyday, the operation, located adjacent to the railroad tracks to facilitate shipping of assembled trusses and girders, was the largest employer in Manasquan. The firm marketed bridges nationally, and it is known that they produced spans for Portland, Maine and Grand Rapids, Michigan. The company produced many types of bridges from multi-span pin-connected Pratt through trusses (1903 North Park Street Bridge in Grand Rapids) to large rivet-connected swing spans (1906-07 Vaughn Bridge, Portland, Maine). It is also historically significant that a relatively small designer/fabricator like the New Jersey Bridge Company continued operations after the creation of the American Bridge Company conglomerate in 1901. The 1903 swing span is the oldest moveable span over Rancocas Creek, an important county waterway and transportation route prior to World War I.

The bridge is located at Centerton, a village in Mount Laurel township. About 1880, the village was composed of nine or ten dwellings. Centerton has been the site of a crossing of the tidal creek since 1832. Centerton was the site of a phosphorous manufacturing plant established in 1877-78. The products, which included matches, were shipped to Philadelphia. The factory is not extant.

Boundary Description and Justification: The bridge is evaluated individually eligible because of its technological and historical merits, and is thus not dependent on its surroundings for its significance. Hence the boundaries should be limited to the right-of-way of the roadway the bridge carries and the substructure, including any wingwalls.

SETTING / CONTEXT The bridge is carries a 2-lane road over a minor water feature in a wooded setting.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Although altered in 1957 with slab extensions added to each side of the originally 18' wide reinforced concrete arch, the span is one of the few statewide examples of a patented Luten design, and it is illustrated in his National Bridge Co.'s 1907 catalogue. Ferro-Concrete Co., Luten's regional agent, built several spans in Burlington County before WW I. This span is the most complete of the lot, and it is historically and technologically distinguished because of association with Daniel Luten.

INFOR MATION

Bibliography:
Ferro Concrete Company Harrisburg, Pennsylvania 1908 Catalogue (in possession of Victor Darnell, Kensington, CT). Burlington County Engineer. Bridge File: C-4.13.

Physical Description: Built in 1906 as an approximately 18'-wide earth-filled, reinforced concrete deck arch bridge with a clear span of 32', the span was widened on both sides with prestressed concrete slabs on concrete abutments in 1957. Any original railings or parapets were demolished to accommodate the widening, and the limits of the 31'-wide roadway are now marked by modern beam guide rails. The arch spandrel walls are plain.

Historical and Technological Significance: The 1906 reinforced concrete barrel arch bridge is significant as one of the best examples of a patented Daniel Luten arch bridge in the state (Criterion C). Luten (1869-1946) was a highly successful promoter and patent holder of details for reinforced concrete arch bridges. He appears to have possessed keen business acumen in addition to his skills as a Purdue University-educated civil engineer, as he recognized early on the value and broad application of reinforced concrete bridge technology. Luten received his first patent for a reinforced concrete arch detail in 1899 (649,643), and he received at least 14 more before the first world war. More than his engineering genius was his ability to market efficient, reasonably priced, low-maintenance spans to county engineers all over the country. Luten established the National Bridge Company, based in Indianapolis, to promote his patented designs. The designs were marketed nationally through a network of companies that served as regional representatives for Luten in places like Chicago, Berlin (Connecticut), Topeka, and Los Angeles. Locally he was represented by the Ferro-Concrete Co., initially located in Philadelphia, according to National Bridge Company's 1907 catalogue, and then in Harrisburg, Pennsylvania. Through this network of representatives, Luten marketed literally hundreds of bridges throughout the country with the highest concentration being in the Mid-West. Thus, Daniel Luten represents as much the marketing side of engineering as he does the application or development of technology. His reputation is based in large part on his being very successful at recognizing a market and promoting his own designs.

The Ferro-Concrete Company operated in Harrisburg from 1908 through 1925, according to Harrisburg city directories. It appears that the firm peaked during the 1910s, as it had only 5 employees in 1922 (Industrial Directory of the Commonwealth of Pennsylvania). Ferro-Concrete Company was primarily a small bridge contracting firm noted more for its association with Luten's National Bridge Company than anything it did on its own. Several multi-span concrete arch bridges from the 1910s have been identified in Pennsylvania including the Third Street Bridge over the Lehigh River in Easton, Pennsylvania. It is known that the company built bridges in Burlington and Middlesex counties in New Jersey, but their work has not been located anywhere else in the state. Burlington County, in particular, employed Luten's designs and Ferro-Concrete's erection as early as 1906. This arch and the 1909 bridge at Kirby's Mill in Medford Township (03D4570) are documented as having been built by the Ferro-Concrete Co. as was the 1911 reinforced concrete slab span that carries Chesterfield-Sykesville Road over Blacks Creek in Chesterfield (03F2320). Original plans for the Centerton bridge were not located, so it is not known what patented details the bridge contains.

All three of the documented Ferro-Concrete Co. bridges in the county have been altered, but the Centerton Road arch span is evaluated as significant because it retains more integrity of original design than the others. While the 1957 slab additions are not compatible, the original structure is readily discernable. The historical significance of being associated with one of the early nationally recognized proponents of reinforced concrete arch bridges outweighs the distraction of the alteration. The 1906 bridge stands as a record of the development and promulgation of reinforced concrete arch spans in the first decade of this century. Its historical significance is enhanced by the fact that the bridge was also used as an illustration in Luten's 1907 catalogue, which identifies the 32' arch as being in Hartford in Burlington County. It is the only New Jersey bridge in the nationally distributed catalogue.

Boundary Description & Justification: The bridge, located in a wooded setting, is evaluated as individually eligible for its technological and historical significance. Therefore, the boundaries of the significant resource are limited to the 1907 superstructure and substructure, including wingwalls, of the bridge itself. The 1957 slab additions are not significant.

SETTING / CONTEXT The bridge carries the two-lane county road over Parkers Creek in an area of heavy vegetation, making access to the bridge difficult. The surrounding area is a mix of commercial development and scattered farming about 1/2 mile east of the village of Hartford. The road parallels Conrail, which follows a RR right-of-way dating to the Camden and Burlington County RR in the 1870s.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY According to county records, the encased stringer bridge dates to ca. 1910. In 1930, William C. Cook, Inc., a Mount Holly contractor, widened the bridge by adding encased stringers and a reinforced concrete deck to the north side. The bridge has typical mid-twentieth-century balustrades and modern guide rail approaches. It also carries a utility pipe along one side. The abutments are reinforced concrete. The bridge is neither technologically nor historically distinguished.

SETTING / CONTEXT The one-lane bridge over a minor stream is fenced off and closed to all traffic. In a isolated wooded setting at the end of a lightly traveled road, it lies about 1/4 mile north of the NJ Turnpike and is adjacent to the Florence Industrial park.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 6-panel rivet-construction Warren with verticals pony truss bridge has unusual floor beam connections. The floor beams, which extend beyond the deck and support knee braces, have paired filled-top or saddle-like hangers that suspend the beams from the gusset plates at the panel points. The span is very well preserved, but the ca. 1889 rubble-coursed stone abutments were parged in 1991. The seldom-seen floor beam connection makes the span technologically distinctive and significant.

INFOR MATION

Bibliography:
Burlington County Engineer's Office. Bridge File D3.76.

Physical Description: The light 1904 6-panel Warren pony truss bridge is supported on ashlar abutments built in 1889. They were coated with concrete in 1991, covering the original date stone. The trusses themselves are in a more complete state of preservation, and with the exception of replacement of deteriorated lower chords and bearing plates in 1954, appear unaltered. Of riveted construction, the lower and upper chords as well as the diagonals are all composed of angles. The knee braces that extend from the floor beams to the upper chord are original as is the pipe railing on the inner face of the trusses. What gives the span its technological significance are the unusual and possibly unique floor beam hangers. Each floor beam is suspended at the panel point from the oversized gusset plate by a pair of hairpin hangers with filled tops or saddles that are fitted over the gusset plate. The detail appears to be original. The deck is a plank inkind replacement of the original.

Historical and Technological Significance: The 6-panel Warren pony truss bridge built in 1904 is a well preserved example of a once-common bridge type in Burlington County, and it is technologically significant because of its unusual and possibly unique floor beam hanger detail (Criterion C). Fabricated during the period of transition from pinned to riveted field connections, the 76'-long span is all riveted with the exception of the floor beam connections at the lower panel points. The floor beams are suspended from large hairpin hangers with filled tops that straddle the oversized gusset plates. The detail has been identified on no other truss bridge in the state. The county engineer has no original plans for the bridge, so it is not known who designed or fabricated the span. The detail, however, is idiosyncratic and reflective of the experimental nature of truss bridge designs.

Boundary Description and Justification: The bridge is located in an isolated, undeveloped setting. Since it is the bridge that is individually significant, the eligible limits include on the substructure and superstructure.

 # SPANS 1 **LENGTH** 35 ft **WIDTH** 19.6 ft

CONSTRUCTION DT 1853 **ALTERATION DT** **SOURCE** COUNTY ENGINEER

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries one lane of traffic on a side street in Mount Holly, a town that was historically a commercial crossroads because of the Rancocas Creek. Mount Holly, known as "Bridgetown" in the eighteenth century, has an extensive 18th-19th century historic district. Immediately surrounding the bridge are early twentieth-century residences, although the stone foundations, some of which are contiguous to the bridge, probably date to the 19th century.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. Mount Holly Historic District. 02/20/1973. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY A plaque and scant county records support an 1853 construction date for the small brick arch bridge, the only one of its type in the area. The spandrel walls are rubble-coursed stone. The spandrels have been raised with brick extensions that appear to be an addition. The intrados and the inside of the parapets have concrete parging. The east end of the north parapet wall looks reconstructed. The bridge, second oldest in the county, is individually eligible for listing in the National Register of Historic Places under Criterion C, and it contributes to the character of the Mount Holly Historic District.

INFOR MATION

Bibliography: Burlington County Engineer's Office. Bridge File #D4.18. ONJH "Mount Holly Historic District" National Register nomination. 1973.

Physical Description: The elliptical brick arch bridge with a span of 35' is founded on ashlar footings and had a rubble-coursed stone spandrel wall. The footings have been reinforced with concrete skirting. The parapets are brick, and their inner face has been covered with a cementous coating as has the intrados of the arch. A date stone is located on the inner face of the parapet. The bridge crosses a small non-navigable branch of the Rancocas Creek. It is located in a 19th century residential area dominated by 2- and 3-story town houses. The arch appears to be sound.

Historical and Technological Significance: The small brick arch bridge is one of the few example of its type in southern New Jersey, and it is therefore a technologically significant span. Brick arches do not appear to have ever been a common bridge type, and there are less than half a dozen documented as surviving in the state. The documented incidence of brick arch spans places them in the second half of the 19th century with this example in Mount Holly ranking as one of the earliest. No original plans for the bridge survive with the county engineer, and the date of construction is established by a plaque and scant county records.

In addition to its technological significance, the bridge is located within the Mount Holly Historic District. The well-preserved assemblage of 18, 19th, and early 20th century buildings is significant in several areas including architecture, commerce, and transportation, and the bridge, built during Mount Holly's period of significance, contributes to the historic character of the community.

Boundary Description and Justification: The bridge is located within the Mt. Holly Historic District, so the entire area surrounding the bridge for some distance has been evaluated as eligible and contributing to the historic character of the district.

DESIGNER/PATENT UNKNOWN **BUILDER** H. B. SMITH CO.

SETTING / CONTEXT The wide one-lane bridge carries light local traffic over the north branch of the Rancocas Creek in Smithville, a company town named after the flamboyant manufacturer Hezekiah B. Smith. The H.B. Smith Company, founded in 1865 to make woodworking machinery, was also famous for making the Star bicycle and the bicycle railroad between Mount Holly and Smithville in the 1890s.The Smithville Historic District includes the river and lake area, which is now a park.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. Smithville Historic District. 05/12/1977. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY When the stringer bridge with unusual cast-iron X-shape pile caps and cast deck brackets or clips on the fascia stringers was built is not documented, but the details make it a historic and technologically distinctive span. It is likely that the pile caps, supported on timber piles, were designed and produced by the H.B. Smith company, a noted manufacturer of woodworking machinery prior to 1926. It is known that the bridge was in place in its present configuration by 1890.

INFOR MATION

Bibliography:
Bolger, William. Smithville, The Result of Enterprise. Burlington County Cultural and Heritage Commission. 1980. Burlington County Engineer's Office. Bridge File # D4.13.

Physical Description: The 56'-long 3-span stringer bridge with a vertical profile and one simple and two continuous spans is supported on ashlar abutments and unusual, possibly unique cast iron X pile caps that fit over timber piles. The X-shaped pile caps are arranged four per bent and support a cast iron pier cap with cast clips to attach to the stingers. The pipe railing is affixed to the fascia stringer with bracketed ends on the cast posts that hold the pipe rails. Remedial work to the span includes rebuilding (specific work elements undefined) in 1940 and strengthening the original stone abutments with concrete buttresses and skirting. The concrete deck dates to 1978. The bridge is an idiosyncratic design and is well preserved considering its late-19th century date of construction.

Historical and Technological Significance: The exact date of construction of the unusually detailed stringer bridge is not precisely documented, but historic photographs of Smithville, the 19th century industrial village on the banks of the Rancocas Creek east of Mount Holly, show that it was in place by at least 1890. It is located within the National Register-listed Smithville Historic District (criteria A, C), and it is a contributing element. County Records indicate that it was built by the H.B. Smith Company, and it is likely that it was in fact designed by Hezekiah B. Smith (1816-1887) or his engineers as part of the his improvement of the former Shreve cotton textile mill complex Smith purchased in 1865. Smith vastly expanded both the water-powered manufacturing facility for his highly successful and technologically innovative manufacture of woodworking machinery, a concern that continued into the 1950s. Smith also expanded the nuclear village that surrounded the works. The iron and steel bridge ranks as one of the earliest and most unusual stringer bridges in the state. Its significance is derived from both its historic association with Smithville, a significant industrial site, and its unusual design. It is reflective of the technological ingenuity of inventor and manufacturer H.B. Smith.

Boundary Description and Justification: The bridge is located within the Smithville Historic District. The area all around the bridge is part of the district. See ONJH's Burlington County National Register file of a map delineating the exact boundaries of the district.

DESIGNER/PATENT JAMES LOGAN, COUNTY ENGINEER **BUILDER** MEDFORD CONCRETE COMPANY

SETTING / CONTEXT The bridge carries two lanes of the county road over Stop the Jade Run on the edge of Vincentown. The river marks the north boundary of the Vincentown Historic District, which celebrates the town's history as a milling center and its surviving residences from several eras. The immediate vicinity of the bridge is lightly wooded with 19th and 20th century residences within 100 yards.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Vincentown Historic District 09/21/1988. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span concrete-encased steel stringer, built in 1915, rests on masonry abutments built in 1907. The south abutment has a 1936 concrete addition at its base to control erosion. The center pier is reinforced concrete. The bridge has a nice decorative metal railing in poor condition made by the Canton Bridge Company. Except for the railing, the bridge lacks technological distinction but it does correspond to the historic district's period of significance and is thus contributing.

INFOR MATION

Bibliography:

ONJH. "Vincentown Historic District." 1988.

Physical Description: The 2-span simply supported encased stringer bridge is supported on ashlar abutments built in 1907. The central pier is reinforced concrete. What happened to the previous superstructure is not known. A sidewalk is carried on the east side only. In 1936 a concrete facing was added to the south abutment. The bridge is enclosed by a handsome lattice iron railing with cast iron posts.

Historical and Technological Significance: The encased stringer bridge, built in 1915 on 1097 stone abutments, is a representative example of a common bridge type in the state, but it is located on the boundary of the Vincentown Historic District that is recognized for being an architecturally and historically distinguished residential, commercial, and milling center. The period of significance of the village extends through the 1920s, so the bridge was built within its era of significance and is a contributing resource. The handsome, well-preserved iron railing of the bridge, manufactured by the Canton (Ohio) Bridge Company, according to the plaque, contributes to the historic character of the district. The concrete-encased superstructure was erected by the Medford Concrete Company.

Boundary Description and Justification: The bridge is located across the water course that forms part of the north boundary of the Vincentown Historic District. It is appropriate to consider the north bank of the water course the boundary, which would then include the bridge within the boundary of the historic district. The limit of the boundary of the district clearly does not extend beyond the north bank of the water course.

SETTING / CONTEXT The bridge carries a 2-lane street and sidewalks over a minor stream in Vincentown's historic district, which celebrates the town's history as a 19th- and early-20th century milling center and its surviving residences from several eras. Mill St. was named after the grist and sawmills that first grew up in the town between 1800 and 1820. A church, 19th and 20th century residences, and a commercial buildings are in the immediate vicinity of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Listed. Vincentown Historic District 09/21/1988. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span concrete encased steel stringer bridge rests on reinforced concrete abutments. In 1981, the county made minor concrete repairs to the headwalls, curbs, and facing. The bridge has metal railings and also carries a utility pipe. Although a common bridge type and not individually distinguished, the span was built within the district's period of significance that extends to 1930. It thus contributes to the historic character of the district.

INFOR MATION

Bibliography:

ONJH. "Vincentown Historic District" National Register nomination, 1988. Burlington county Engineer. Bridge File D4.27.

Physical Description: The single-span, 38'-long encased steel stringer bridge is supported on concrete abutments. The sidewalks are enclosed with metal, fence-like railings while the approaches are marked with concrete parapets.

Historical and Technological Significance: The steel stringer bridge is not technologically distinguished, but it is located within the National Register-listed Vincentown Historic District, and it was constructed within the period of significance of the district that extends through the 1920s. Vincentown, which retains its pre-1930 appearance, was an important country commercial and milling center through World War I. The bridge, a well-preserved example of an extremely common bridge type, contributes to the historic character of the district.

Boundary Description and Justification: The bridge crosses a water course that is located within the Vincentown Historic District. Because the bridge is in the "heart" of the district, all the area surrounding it is considered eligible. For a map of the exact district boundaries, refer to the ONJH's Burlington County National Register file.

SETTING / CONTEXT The bridge carries a 2-lane street over the south branch of Rancocas Creek in Vincentown's historic district, which celebrates the town's history as a milling center and its surviving pre-1930 residences from many eras. The dam that forms the mill pond south of the town is adjacent to the bridge. There are six timber sluice gates directly below the south fascia of the bridge. The bridge is in a municipal park.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Not Individually Eligible. Listed. Vincentown Historic District 09/21/1988. Contributed.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased steel stringer bridge rests on reinforced concrete abutments with wing walls. The bridge has pipe railings, and the sluice gates and frames for the mill pond dam are timber. The span is a representative example of a common type, but it was built within the period of significance of the Vincentown Historic District, which extends to 1930. While not individually significant, it does contribute to the history and character of the district.

INFOR MATION

Bibliography:

ONJH. "Vincentown Historic District" National Register Nomination. 1988.

Physical Description: The 35'-long encased steel stringer span is supported on concrete abutments with wing walls and is enclosed by a pipe railings. The upstream side of the simple, well preserved bridge is fitted with wood frames holding manually operated wood sluice gates for the adjacent mill pond.

Historical and Technological Significance: Although a representative example of a common New Jersey bridge type, the stringer bridge is historically significant because is it was built within the period of significance (18th century through the 1920s) of the Vincentown Historic District. The bridge crosses a stream that was dammed to create a mill pond that powered the community's mills that were active until the early years of the 20th century. Although this is not the original bridge at this crossing, it is nevertheless a contributing structure in the historic district based on its date of construction and appearance. Vincentown is a community that retains its pre-1930 appearance, according to the National Register nomination.

Boundary Description and Justification: While not individually significant, the bridge is located in the "heart" of the Vincentown Historic District. It is surrounded on all sides by eligible property. For a map of the exact boundaries of the Vincentown Historic District, refer to ONJH's Burlington County National Register files.

CONSTRUCTION DT 1909 **ALTERATION DT** 1989 **SOURCE** PLAQUE

DESIGNER/PATENT UNKNOWN (D. LUTEN ?) **BUILDER** FERRO CONCRETE CO.

SETTING / CONTEXT The bridge carries a 2-lane road over the head race for Kirby's Mill approximately 40' from the turbines. The complex, first built in the 1770s included a 3 1/2 story grist mill, sawmill, shingle mill, carding mill, blacksmith shop, and other structures. The grist mill operated under water power until 1961, the last to do so in New Jersey. It closed in 1969. The well preserved complex is located on a small island, and it is listed in the National Register.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Kirby's Mill. 08/12/1971. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 20'-wide deck arch bridge built in 1909 was partially rebuilt in 1989. Four feet were added on each side and concrete parapets were reproduced. While the span retains some degree of original detailing of the 1909 span, the proportions of the superstructure and the roadway that pass through the center of the historically significant mill complex disrupt the original historical character of the surroundings. The altered span is evaluated as noncontributing based on alterations and proportions.

DESIGNER/PATENT J. LOGAN, BUR. CO. ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries the two-lane county road over the North Branch Rancocas Creek in Smithville, a 19th and early 20th century company town named after flamboyant manufacturer Hezekiah B. Smith. The H.B. Smith Company, founded in 1865, produced woodworking machinery, the Star bicycle, and the bicycle railroad between Mount Holly and Smithville.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Smithville Historic District. 05/12/1977. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 7-span continuous concrete slab, built in 1914, rests on reinforced concrete piles, pile caps, abutments, and wingwalls. It is finished with the original pipe railing. The piles are spalled. In 1951, most of the members were gunited. In addition to being built within the period of significance of the Smithville Historic District, the span is technologically distinguished as being an early example of a reinforced concrete pile bent-supporting a slab deck bridge. The bridge is individually eligible for listing in the National Register of Historic Places and is a contributing element of the Smithville Historic District, eligible under Criteria A and C.

INFOR MATION

Bibliography:
Burlington County Engineer's File # E4.44. Condit, Carl. American Building Art 20th Century, 1960.

Physical Description: The 7-span bridge is a continuous slab bridge supported on reinforced concrete abutments and reinforced concrete bents composed of five 16" square piles set 6' on center apart and a 34'-deep pier cap. The slab deck is covered by an asphalt wearing surface, and the bridge is finished with the original pipe railing. With the exception of gunite that was sprayed on most of the members in 1951, the superstructure and substructure survive in a good state of preservation.

Historical and Technological Significance: The 1914 bridge is technologically significant because it is an early example of a reinforced concrete driven-pile substructure (criterion C). The original plan of the bridge is preserved in the Burlington County Engineer's Office, and it confirms that the 7-span structure designed by James Logan, Burlington County Engineer in 1914, survives in "as built" condition. Reinforced concrete quickly became a popular and commonly used material in bridge construction in the years between 1895 and 1905, but the applications were primarily for reinforced concrete arch and slab spans. This bridge is one of the earliest documented applications in New Jersey of reinforced concrete technology for supporting piles that make up a reinforced concrete pier bent.

The bridge is located within the Smithville Historic District, but it was built outside the 1800-1899 period of significance of the district specified in the nomination. The nomination does not address the period after H. B. Smith's death in 1897, but the H.B. Smith Machine Company continued in operation until the 1960s.

Boundary Description and Justification: The bridge is located on a road that forms part of the east boundary of the Smithville Historic District. The area on the west side of the bridge as well as the approaches to the north and south are thus within the district. The area east of the abutments is not within the district, and is evaluated as not eligible. The east side of Smithville Road (CR 684) is the appropriate boundary for the district and the bridge.

SETTING / CONTEXT The bridge carries a two-lane road, sidewalks, and a utility pipe over the north branch of the Rancocas Creek in Pemberton, a village that was traditionally an agricultural center for the surrounding region. Located on the edge of the congested portion of the center of Pemberton, it is surrounded by an eclectic mix of structures. The creek is the boundary of the State Register-listed Pemberton Historic District, but the bridge is not evaluated.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Pemberton Historic District. 03/22/1989. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 6-panel rivet-connected Warren with verticals pony truss bridge is composed primarily of latticed and laced channels. The bridge was moved, reconditioned, and set on a new concrete substructure in 1950 when the road was realigned. A steel grid deck was also installed then. The county rehabilitated the span again in 1977. A late example of a truss designed for secondary stresses, the span is not technologically or historically distinguished. It is not fully within the district and is outside the 19th and early 20th century period of significance. It is later than its setting.

CONSTRUCTION DT 1923 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge carries one lane of a rural lightly traveled road over a minor stream in a wooded setting. Late-20th century residential development is adjacent to the bridge. The setting is not significant.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 11/22/91

SUMMARY The 6-span wood stringer bridge is supported on wood braced pile bents and a stone abutment on the east end and a concrete abutment on the west end. The stone abutment predates this span. Modern beam guide rail railings replace any original/early railings. The bridge appears to incorporate modern inkind replacement material. It is a representative example of a common bridge type, and it not historically or technologically distinguished.

DESIGNER/PATENT **BUILDER** FERRO-CONCRETE COMPANY

SETTING / CONTEXT The bridge carries a 2-lane county road over a minor stream just downstream from a mill pond dam. The pond was established as early as the early-19th century. None of the mill-related buildings appear to survive, but the house, shown as the Norden House on the 1876 Scott Atlas Map, remains, but it has been reworked in the Colonial Revival taste. It was later Wallace Mill. The surroundings are wooded. There is modern residential development on the south side of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 01/10/92, Letter 11/22/95. DOE 01/19/95.

SUMMARY Built in 1911 as a 2-span reinforced concrete slab span on a concrete substructure, the bridge is arranged like a 2-cell culvert with an invert slab, and wood flood gates (removed). Built by the Ferro Concrete Co. of Harrisburg, the technology represented by the bridge is one of the state's earliest surviving examples of concrete slab construction. The builder was the local agent for D. Luten's National Bridge Co. and his designs, but no plans survive to show if this is a patented design.

SETTING / CONTEXT The bridge carries the two-lane county road over the Greenwood Branch of the Rancocas Creek on the outskirts of New Lisbon, a village that had a sawmill and forge early in the 19th century. The wood used to build the Camden and Amboy Railroad supposedly came from the New Lisbon area. The bridge is about 1/4 mile from Conrail, which operates on a right-of-way dating back at least to the 1870s. The bridge is also next to a 1935 pumping station.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The one-span steel stringer bridge, built in 1941, has the fascia stringers encased in concrete. The bridge rests on reinforced concrete abutments and wing walls, and has a reinforced concrete deck and railing. The span replaced an earlier timber stringer bridge. It lacks historical or technological distinction.

CONSTRUCTION DT 1916 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT J.J. ALBERTSON, CO. ENGINEER **BUILDER** INTEGRITY CONST. CO.

SETTING / CONTEXT The bridge is located in a mid-20th century commuter suburb and is surrounded by modern commercial development. US 30, known as the Whitehorse Pike was the primary highway between Camden and Atlantic City until construction of the Atlantic City Expressway. Although the road this bridge carries dates to the 18th century, the setting is not historically significant.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The well-preserved and well-proportioned 1916 reinforced concrete arch with a paneled parapet and wing walls is a good example of its structural type. It is one of 8 built by the county between 1905 and 1937. It was designed by the county engineering department under County Engineer J.J. Albertson and is better detailed than most of the other concrete arch bridges in the county. It is technologically significant based on its design and state of preservation.

INFOR MATION

Bibliography:

Camden County Engineer's Office. Bridge File.

Physical Description: The well-proportioned and well-detailed single-span barrel arch bridge of reinforced concrete is a good representative example of its type. it is finished with paneled spandrels and abutments. The parapets are finished with the same shallow panels, and the massive posts have oversized chamfered caps. The bridge carries a wide two-lane road, now part of the state highway system, and two sidewalks over a tidal creek.

Historical and Technological Significance: The handsome reinforced concrete arch bridge was built in 1916, and it is a good, representative example of a concrete arch span, a significant period technology. It is the best detailed and example of the bridge type in the county (criterion C). Introduced into this country in the late-1890s, the reinforced concrete arch became immensely popular for crossings under 60' in the 1900s and 1910s before being eclipsed by the encased steel stringer bridge. The structure was designed by the Camden County Engineer's Office, J.J. Albertson, County Engineer. The original plans are preserved in the Engineer's office, and they show that the bridge has not been altered. The US 30 bridge is the best of six similar spans built by the county between 1915 and 1919, and that is why it is evaluated as significant.

Boundary Description and Justification: The bridge is evaluated as individually significant based on its type and detailing. Its setting is not well preserved. Therefore, the boundary is limited to the substructure and superstructure of the span itself.

SETTING / CONTEXT The bridge is in an extensively developed commercial corridor that is an approach to the 1926 Ben Franklin Bridge. It carries a non-distinguished 8 and 10 lane limited-access road initially improved as part of the Camden Extension project. Historically there was some industrial activity along the river in the vicinity of the bridge, river traffic ceased about 1960. Much of the surrounding area has been cleared.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Not Individually Eligible.
CONSULT DOCUMENTS SHPO Finding 6/30/93

SUMMARY Each leaf of the double-leaf trunnion bascule bridge is composed of four haunched girders. The racks and pinions power the inside girders. The gear sets are in place but inoperable. Two-story operator/mechanical houses are located at each corner. While the span retains its original appearance, it has been inoperable since about 1968. It has lost integrity of original design. It is one of at least a dozen Ash, Howard, Needles & Tammen movable bridges in the state. Others are more complete.

INFOR MATION

Bibliography:
Hanover & Hardesty. Inspection Reports, 1970, 1980. Brown, Kathi Ann. Diversity By Design. 1989. U.S. Patent 1,633,565.

Physical Description: The main span of the 3-span bridge is a 171'-long double leaf trunnion movable span of built-up haunched deck girders. Because the bridge is wide, 118' out-to-out, each leaf is composed of four girders. The cantilevered sidewalks are carried on brackets attached to the outside girders. The sidewalk is enclosed by a standard state design metal railing. The roadway, now 88'-wide, was widened from 76' wide in 1952 by taking 5' from each sidewalk. The steel grid deck, replacing the original wood block pavers, was placed at that time. The substructure is concrete with the counterweight pit walls also serving as the abutment and trunnion columns supports. The concrete counterweight is affixed to the tail end of each leaf.

The bridge was operated by two electric 125-horsepower motors and open reducer gear sets. Racks are attached to the inside girders and moved by drive pinions. This tandem arrangement is common. The back up power was supplied by 35 horsepower gasoline engines. Neo-classically inspired reinforced concrete and brick houses, each with a shallow hip roof, are located at each corner of the movable span with the one in the southwest corner being the operators house. Windows, originally small-light metal casements, are primarily boarded, and access to the interior of the house was not possible. Electrical service was disconnected by at least 1975. The electrical system was reported to be in "badly deteriorated" condition in 1970. The original crash/safety gates have been completely removed as have navigational lights.

The bridge is not operable and is sealed.

Historical and Technological Significance: The double-leaf trunnion bascule bridge was designed in 1926 and built in 1927 on one of the roads built as part of the Camden Extension, a network of existing roads and connectors to improve traffic flow generated by the completion of the Delaware River (Ben Franklin) Bridge in 1926. The Camden Extension, as the project was known, was developed under State Highway Engineer William S. Sloan, and it was one of several late-1920s programs by the State Highway Department to address traffic related to major river crossings on both the Delaware and Hudson rivers. The plan for access to the Delaware River Bridge was to use a new connecting road to link the old Burlington Pike (NJ 2), the Moorestown Pike, the Whitehorse Pike, and NJ 6, the road to Millville, as well as many other roads that lead to Camden. The connecting road joined the entrance road through Camden to the bridge toll plaza. Traffic circles were used along the route as a means of addressing unimpeded traffic flow. The Camden Extension is not distinguished by innovative solutions to crossings; they are typical solutions to common problems.

The Cooper River bridge was built on the entrance road portion of the Camden Extension. The bascule portion was designed by the consulting engineering firm of Harrington, Howard & Ash, which was established in 1914 after the dissolution of the Kansas City, Missouri firm of Waddell & Harrington. Harrington, Howard & Ash opened their New York City office in 1922 with Enoch Needles (1888-1972) as its head. The office saw the East Coast, with its numerous private toll bridge commissions and state highway departments, as a great potential market for its movable span bridges. The firm, initially founded by J.A.L. Waddell, the engineer who developed the modern vertical lift bridge, went on in the 1920s to become the most prolific designer of trunnion bascule bridges in New Jersey, thanks in large part to the reputation of its New York office. Harrington left the firm in 1928, after which it was styled Ash, Howard, Needles & Tammen (AHNT) and is Howard, Needles, Tammen & Bergendoff (HNTB) today.

The patented detail involved with the design of all AHNT's bascule bridges in New Jersey relates to the trunnion column which provides "improved span support, braced to resist the various stresses to which it is subject at different positions of the span, and to provide supplemental support of the free end of the fixed span at all times." The movable span itself was a traditional trunnion bascule with a fixed counterweight at the tail end. This design requires satisfactory clearance above mean high water or else a counterweight pit, like that at the Cooper River Bridge, to keep the counterweight out of the water when the bridge is open. At least a dozen trunnion bridges designed by AHNT between 1927 and 1942 survive in the state and are located in Bergen, Monmouth, and Cape May counties with the most complete being two built in Monmouth County in 1932 and 1939 (1300S31 and 1315150) and four built by the Cape May County Toll Bridge Commission in 1938-1940 (3100003, 0500028, 3100005, 3100006). Those examples still operate, are complete with their original

operating mechanism, and enjoy integrity of setting.

The Cooper River bridge has lost integrity of original design in that it no longer functions as a movable span bridge. It last opened prior to 1968, and since that time the electrical service has been removed as have the safety and navigation equipment. The bridge was sealed about 1968. While the gearing remains in place, it has been unmaintained for about 25 years, and the electrical equipment, including the drive motors, is inoperable. The operators house and mechanical houses are unaltered, but they too have not been maintained. In addition to the loss of integrity and thus technological significance due to disuse and deterioration, the setting of the bridge has also been altered through decline of the businesses that once relied on water-borne transportation. Much of the surrounding area has been cleared.

The Cooper River bridge is one of the earlier examples of the popular AHNT bascule design, but it is the same design as other more complete examples. It represents a bridge type and design, the trunnion bascule, that was common technology by the mid-1920s. The Cooper River bridge is also the newest of movable span bridge on the Cooper River at Camden. The other two, the 1906 Strauss overhead counterweight bridge at Federal Street (0406159) and the 1898 center bearing swing span thru truss bridge at State Street (042A001), are both historically and technologically significant. The State Street span is in operable condition, and both bridges were built in response to Camden's importance as an industrial center.

SETTING / CONTEXT This structure connects the industrial Cooper River area with downtown Camden. It crosses US 30 (Admiral Wilson Blvd.), the approach road to the Ben Franklin Bridge and main link between Camden and center city Philadelphia. North of the structure is the 20th-century industrial area that lines the Cooper River, and to the south is the downtown business district of Camden. Numerous modern intrusions have made the area not historic.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The thru girder main span is the only original feature of the bridge, built in 1925 as 14-span viaduct to carry Federal Street, a main city thoroughfare, over the newly built Ben Franklin Bridge approach road. It has been altered twice, so it has little integrity. In the 1950s US 30 (feature crossed) was widened considerably, and the approach spans and supports were changed. The bridge was rehabilitated in 1971, date of the present railing.

SETTING / CONTEXT The bridge, built for 3 tracks but carrying only one active line, is located in downtown Camden over busy NJ 30, a half a mile southeast of its junction with the toll booths for the Ben Franklin Bridge. NJ 30 is a divided 6-lane road with a 2-lane access ramp on the north side. The overpass carries all 8 lanes of traffic. The rail line was the PA RR's line from its Camden terminal at the end of Federal St. to Trenton. The bridge was part of the Camden Extension improvement.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 208' long 3-span simple thru girder bridge is supported on concrete abutments and columns. The main span was built in 1927 as part of the Camden Extension. The present approach spans, columns, and abutments were built in 1971. The bridge is one of over 10 thru girder overpasses built in the county between 1927-1933. The main span is a representative example of a locally common structural type and is not individually noteworthy, especially in light of the 1971 alterations.

DESIGNER/PATENT **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries 2 tracks of ConRail's Clementon Branch over US 130, a 6-lane limited-access divided highway. It is located in an early 20th-century commuter suburb in mixed use area with both industrial and residential areas within sight. The north side of the bridge is obscured by a 1955 overpass. Initially developed by the Philadelphia and Atlantic City RR in 1877, the rail line became part of the Reading system in 1883. It was their main line to Atlantic City and Cape May.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The continuous slab 2-track overpass has concrete abutments and piers with open arched spandrels and a concrete parapet with paneled posts. It is unaltered and appears to be an infrequent application of slab bridge technology to a rail-carrying span in the area. It is however, not an innovative or early use of reinforced concrete in railroad bridge construction. It is not technologically distinguished. Another multi-span slab overpass is located in Gloucester County (0805154).

INFOR MATION

Bibliography:
Condit, Carl. American Building Art 20th Century. New York: Oxford University Press, 1960. NJDOT. File 6104.

Physical Description: The well-proportioned skewed 4-span reinforced concrete continuous slab bridge is supported on scored concrete abutments with wing walls and concrete piers with arched struts and paneled square column end posts. The parapet is detailed with blind panels and posts as well as larger paneled posts defining the span lengths. The ballasted deck bridge appears to be unaltered.

Historical and Technological Significance: The handsome, well-proportioned span is a rare state application of a slab bridge technology to a rail-carrying overpass. Approximately half a dozen have been identified on rail lines not managed by New Jersey Transit, and this example, built by the Reading Railroad in 1927 on its main line from Camden to Atlantic City, ranks as the most ambitious in size and detailing. It is also well preserved.

Flat-slab construction (e.g. mushroom column) was adapted to bridge construction in 1909 by the Soo Line in St. Paul. It reached its greatest length at Brick Church, New Jersey on the DL&W line, a national leader is the application or reinforced concrete technology to railroad use. It is not however, a common bridge type for railroad overpasses in the southern two-thirds of the state. No plans for the US 130 bridge were located, so the reinforcing system is not known.

The east side has been redeveloped with a large post-WW II housing project while the west side is 19th-century urban residential and commercial. The bridge is just south of the confluence of the Cooper and Delaware rivers. It is an important transportation link in the development of the community.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY A pin-connected hybrid type thru truss center bearing swing span on ashlar abutments and central pier has some repairs and modifications, but it remains the oldest and most complete example of its type in the area. The 1977 rehab work is not intrusive, and new elements are compatible with the original design of the bridge. It is the earliest extant crossing of the Cooper River in Camden, a city noted for its 20th century industrial heritage. The bridge is of historic and technological value.

INFOR MATION

Bibliography:
AGLAS Inspection Reports. Camden County Engineer. File A1-21.

Physical Description: The pin-connected 8-panel Warren thru truss center bearing swing span bridge is supported on a circular ashlar center pier and ashlar abutments with concrete bearings added in 1976. The end posts, diagonals, and verticals are composed of laced angles, and eye bars are used as the diagonals in panels where no compressive load was anticipated. The original operating machinery appears to have been replaced in 1928, and it is still in place, although the 1928 electric motor was replaced in 1976. Other modifications to the span include new floor beams, sidewalks and corresponding railing, and new wedges, all installed in 1976. The portal braces are not original, but they were on the bridge by 1955. Repairs have been made to the trusses themselves as needed. The operators shanty is at the southwest corner of the bridge. Despite the many modifications and repairs, the span survives as one of the more complete thru truss swing spans in the region.

Historical and Technological Significance: The State Street Warren thru truss center-bearing swing span bridge was built in 1898 by contractor B.F. Sweeton & Son. The designer is not known. No original/early plans of the bridge were located. Despite the lack of documentation related to the designer and builder, the span stands as one of the most complete 19th-century highway thru truss center-bearing swing spans in the state. The bridge type represents one of the oldest types or mechanically operated moveable bridges, and although once a common late-19th and early 20th-century bridge, swing spans were frequently replaced by trunnion or vertical lift spans that provided a wider clear channel and faster openings. The State Street Bridge represents an important early technology that was eclipsed in urban settings, for the most part, by 1910. Despite the modifications to its original design, the bridge retains its integrity of original design and function.

Boundary Description and Justification: The bridge is evaluated as individually significant. Its original setting has been cleared and, in areas, redeveloped. Therefore, the boundary is limited to the superstructure and substructure of the span itself.

SETTING / CONTEXT The moveable span carries Federal Street, a main thoroughfare into Camden over the Cooper River in an industrial area dating to the late 19th century. Until ca. 1960 the river was used by some of the waterfront industries to ship and receive goods.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY One of about 6 overhead counterweight bascule bridges remaining in the state, the patented Strauss bridge was erected in 1906. The rarity of the once-common structural type coupled with its distinctive Beaux Arts concrete detailing combine to make the Federal St. bridge one of the most significant movable bridges in the state. Its decorative concrete detailing reflects the tenets of the City Beautiful movement that dominated pre-World War II civic projects. The span is well preserved.

INFORMATION

Bibliography:
J.B. Strauss Dies at Los Angeles." Engineering News-Record. 120 (May 19, 1938), p. 702. Camden County Engineer. Bridge File.

Physical Description: The single-leaf overhead counterweight bridge is composed of a 78' rivet-connected Warren pony truss moveable span supported on concrete abutments. Cantilevered sidewalks on both sides are enclosed by handsome cast-iron filigree railings while the approaches are protected by concrete parapets with reticulated panels. The overhead counterweight, supported on built-up steel columns, linkage, and operators house are "hidden" beneath the two-level concrete Beaux Arts veneer that transforms the utilitarian and decidedly non-aesthetic elements of the bridge into an elaborate arch or portal finished with oversized consoles, segmental parapets on the corner pavilions, and reticulated panels. The windows in the corner pavilions have been removed, but otherwise the rich classically inspired ornamentation, including some original light standards, is well preserved. Alterations to the original design appear to be few. The original wearing surface has been replaced by a steel grid deck, and modern beam guard rails protect the road side of the trusses. The operating mechanism was not inspected, and it is assumed to remain in place.

Historical and Technological Significance: The 1906 Federal Street Bridge is one of the most significant moveable span bridges in the state because of its date of construction, type, embellishments, and state of preservation (Criterion C). It is a nearly complete example of a patented bridge design that represents a milestone in the development of moveable spans. Its single-leaf trunnion with an articulated overhead counterweight main span was designed by Joseph B. Strauss (1870-1938), the most widely recognized early-20th century moveable bridge engineer in the country. The pivoting counterweight linkage, like that on the Federal Street span, was invented by Strauss in 1905 (patent granted in 1911), and the first span of this type was built in Cleveland, also in 1905, the same year Strauss established the Strauss Bascule Bridge Company in Chicago. His parallelogram-linked counterweight bascule bridges were his best-known design. Once common, the Strauss overhead articulated counterweight bridge is becoming increasingly rare. Only four other highway examples are known to remain in New Jersey, and of that total, only one other dates to the 1900s.

The Federal Street Bridge is not only a very early example of the patented design, it is also one of the most architectonic bridge in the state. It is the only documented example of its type in the region with the an architectonic finish, which gives the bridge national significance. An expression of the City Beautiful philosophy of civic projects, the utilitarian, mechanical aspects of the bridge are hidden behind a classically inspired concrete veneer as richly detailed as a public building. Strauss later adapted his articulated counterweight to the underneath position, and while more expensive, it was frequently the choice for moveable spans in congested, urban settings. The choice was not available to the Camden authorities because it had not been developed yet, so their solution was to disguise the workings of the bridge. A similar Strauss overhead counterweight moveable span bridge was built on Broadway in Camden in 1913, and it too was given architectural embellishments. The tower and mechanical equipment have been removed from the Broadway bridge and the moveable span has been fixed in place.

The Camden County Engineer's nearly complete set of drawings for the Federal Street bridge show that the architectural encasing was delineated on the original plans. The bridge as built, however, does not match exactly with those plans, which specify more detailing than was actually executed.

The bridge has had some modifications and replacement of original fabric, but none of the changes, not the fact that it does not match the plans exactly, compromise the original design and functioning of the span. The deck of the moveable was replaced in 1934, and the counterweight and concrete were repaired in 1974. The bridge ranks as the most significant of all the Strauss overhead articulated counterweight bridges as well as one of the most significant movable spans of any design in the entire state.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to the span itself, and includes the approach and the tower.

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT The bridge carries a 2-lane street through a city park that is surrounded by a post-World War II residential neighborhood. Park is developed with playgrounds and sports fields. The bridge spans a small branch of the Newton Creek.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete arch with a paneled concrete parapet is a representative example of the 7 similar pre-1930 arch spans built in the county. Although well preserved and representative of its structural type, the bridge is not individually distinguished or historical. Reinforced concrete arches came into common use for short spans in the 1905-1910 era, and they were a bridge type that some county engineers greatly favored through the 1910s.

DESIGNER/PATENT STRAUSS BASCULE BRIDGE COMPANY **BUILDER** KELLY MCFELLEY

SETTING / CONTEXT Located in an industrial area of South Camden adjacent to the New York Shipbuilding Company yard and a modern sewage treatment facility, the bridge crosses a tidal creek. None of the adjacent properties are National Register eligible. New York Shipbuilding's facility is now closed, and much of its historic machinery and buildings have been removed. The bridge was constructed as a Strauss overhead counterweight movable span.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 4/30/91

SUMMARY Although built in 1913 as an architectonic single-leaf overhead counterweight Strauss-patent bascule bridge, it is now a simple 2-span thru girder bridge. The counterweight, operators houses, and tower were removed in 1964, and the movable girders are fixed in place. The handsome reticulated metal sidewalk railing remains, but all other ornamentation was lost in 1964. The bridge is no longer significant because it has been so drastically altered. Original plans survive with the county.

 # SPANS 1 **LENGTH** 46 ft **WIDTH** 20.9 ft

CONSTRUCTION DT 1920 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT Located in Audubon, a residential community developed beginning in the 1890s, the bridge carries the main street (E. Atlantic Ave.) over 2-lane Nicholson Rd. It parallels the Atlantic City Div. railroad, 20' to the west, which also crosses Nicholson Rd. on a deck girder bridge. Both bridges, as well as the similar pair 500' to the north are located in an area of Audubon that is not architecturally cohesive enough to comprise a National Register-eligible historic district.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The shallow thru girder with floor beams on concrete abutments is contiguous to a similar but deeper railroad overpass, but the railroad bridge is on earlier ashlar abutments. The 2-lane highway bridge with cantilevered sidewalks and pipe railings is dated 1920 by NJDOT. The only surviving drawing is undated and refers to strengthening the span. It is an early highway grade crossing elimination needed more to keep E. Atlantic Ave. at the same grade as the railroad than to separate traffic.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-proportioned rigid frame bridge with concrete posts and rustic wood railing was built in 1930 as part of the parkway in Cooper River Park. It was built for the Parks Commission. The bridge type was used frequently in the county in the 1930s.

INFOR MATION

Bibliography:
Brown, C. Oscar, editor. Camden County Park System As Constructed by Camden County Park Commission. np, nd. (Xerox copy in collection of Janet Fittipaldi - NJDOT).

Physical Description: The 48'-long rigid frame bridge with an arched soffit is finished with stepped rectangular end posts and rustic-style wood post-and-rail railings. The same railings are used on the reinforced concrete approaches to the span. The bridge appears to survive in original condition, and its setting, in a casually landscaped park, is also well preserved.

Historical and Technological Significance: Although not individually technologically distinguished, the 1930 rigid frame bridge is a contributing element to the potentially historic Cooper River Park Historic District (criterion C). The bridge was the first built by the Camden County Park Commission as a landscape feature in the park. Other bridges that are in or contiguous to the linear park that parallels the Cooper River were not built as park features and are thus evaluated as not contributing to the historic theme of the development of the civic amenity.

County park commissions in New Jersey are as early as 1895, but the Camden County Park Commission was not established until November of 1926. In September, 1927, the new commission defined its goal as "development of the Cooper River valley parks and boulevards from Camden to Haddonfield and beyond (Brown, p. 29). The only section of the boulevard completed before the depression was this section, which was located between Grove Street and Kings Highway. Originally known as section 12, it was renamed Pennypacker Park in 1934 to honor James Lane Pennypacker, the Haddonfield historian and botanist who died in the summer of 1934 (Jones, p. 99). This section of the park was landscaped by the CCCs in the mid 1930s. The bridge was the first and largest built by the park commission, and it was originally fitted with Neoclassical lights atop the end posts. The rustic style of the wood post-and-rail railings were used on other bridges built throughout the greater park system by the CCCs in the mid 1930s.

The Camden County Park Commission was able to complete its ambitious plan for a boulevard from Crescent Boulevard in Pennsauken to Caldwell Street in Cherry Hill only with assistance from the depression-era work relief programs of the federal government. Loans and grants made it possible to complete the road and recreational facilities, and the Civilian Conservation Corps (CCC) did the dredging, filling, masonry, damming, and landscaping that transformed the swampland along the river into a greenway dotted with small lakes and meandering trails. The depression-era, work-assistance programs were responsible for local civic projects like this one all across the country, and they made a significant contribution to the mid-century redevelopment of the nation's urban and open areas. The CCC programs of the mid- to late-1930s did more to develop park land in this country than any other activity short of the initial acquisition of property. Cooper River Park, which is composed of several contiguous sections, is historically significant as an example of the lasting influence and importance of depression-era work-relief programs to recreational spaces in America.

Boundary Description and Justification: The bridge is evaluated as a contributing resource to a potential historic district because it was built as part of the development of the district. It is thus related to the potential historic district by historic association. The bridge, the roadway that it carries, and the land to the south and west of it are in the potential historic district. Bridges in or contiguous to the park that were not built as part of its development do not contribute to the area(s) of significance of the park and were thus evaluated as not significant.

SETTING / CONTEXT Located on the line between the city of Camden and Pennsauken Township, the bridge spans ConRail's single track Petty's Is. Branch, a short line built during World War I to serve the industries on Petty's Is. There is a late-19th, early-20th century industrial district to the north of this bridge, and an early 20th-century residential neighborhood to the south. The bridge carries River Road, a highway that runs parallel to the Delaware River between Camden and Burlington City.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete encased stringer bridge, bearing on concrete abutments has a paneled balustrade. It was built in 1917 as part of the spur line to connect industrial Petty's Is. with Pennsauken and PA RR main lines. The well-preserved span is a representative example of the most common pre-WW II bridge type in the state. It is historically significant because of its association with the development of Petty's Island by the Crew Levick Co. The rail line is abandoned.

INFOR MATION

Bibliography:

Cranston, Paul. Camden County 1681-1931. Camden, New Jersey: Camden County Chamber of Commerce, 1931. Halber, Edmund. A History of Pennsauken Township. Pennsauken, New Jersey: Pennsauken Historical Society, 1966.

Physical Description: The 36'-long concrete-encased steel stringer span is supported on concrete abutments with sloped wing walls. It carries a two-lane road and sidewalks over a two-track railroad right-of-way. The flat-panel parapets at both the road and sidewalks have deeply incised scoring, and the end post are finished with chamfered tops. While simply detailed, the bridge is well proportioned and well preserved. one set of track has been removed.

Historical and Technological Significance: The short encased stringer span is historically significant for its association with Petty Island, a major industrial site in Camden County. The island had various uses from Colonial times through the early 20th century. In 1916 it was acquired by Crew Levick Company, a subsidiary of Cities Services Company. Crew Levick initially the island refining and manufacturing mineral and lubricating oils. In 1920 the bulk fuel oil storage capability was added to the island, and in 1925-27 the refinery was built. The island was linked to the main line of the Pennsylvania Railroad by a spur built in 1918, the same year a rolling lift railroad was bridge built by the Bethlehem Steel Company was completed. This bridge was designed by the Pennsylvania Railroad, but the builder is not known. Materials and products were shipped to the plant by both sea and rail, and Petty Island became a major production and distribution center of petroleum products as well as one of the largest employers in the area. The spur line was, until the early 1980s, the island's only transportation link with the mainland. The moveable span railroad bridge was demolished in 1991, leaving the River Road overpass as the only original railroad bridge historically associated with the Cities Service's development of the island. The island flourished as an industrial site due to its strategic location in the Delaware River opposite Philadelphia.

It is the middle of the 3 nearly parallel rail lines. The surroundings are undistinguished and sparsely developed. The rail line is the right-of-way used jointly by the Pennsylvania and Reading systems as a turnout from the main line to Atlantic City to their Cape May routes.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The riveted steel Warren pony truss with built-up braced verticals was built in 1906 by the American Bridge Company. It is supported on deteriorating concrete abutments. The pipe railing is original as are the handsome cast iron posts on the south end (north end removed). Alterations include new floor beams and stringers and some welded repairs to the diagonals on the north end. The bridge is significant as the only pony truss in the county and one of the best preserved in the region.

INFOR MATION

Bibliography:
Cook, W. George and Coxey, William J. Atlantic City Railroad. Ambler, Pennsylvania: Crusader Press, 1980.

Physical Description: The single span rivet-connected Warren pony truss span is supported on concrete abutments. Its design differs from the traditionally composed pony truss in that it has moment-resisting top chord members composed of a web set between angles. The design redistributes secondary stresses in bending. The verticals are knee braces while the diagonals are back-to-back toe-out angles. The pipe railings with handsome cast-iron end posts are original. The are many small welded and bolted repairs, but the overall design of the bridge is preserved.

Historical and Technological Significance: The well-preserved rivet-connected Warren pony truss bridge is the only example of its type in Camden County. It was fabricated in 1906 by the American Bridge Company, the largest bridge-manufacturing firm in the country. It is a complex truss in that the top chord was designed to be a moment-resisting member that redistributes secondary stresses in bending. It was a somewhat advanced design for its day, and it represents the railroad's transition from pin to rivet connections and moment-resisting design. The design was developed by the railroads during the first decade of this century, and it was used for both rail- and road-carrying spans. It is not a common bridge type, especially in southern New Jersey (criterion C).

The bridge was built by the Atlantic City Railroad (ACRR) as part of its ambitious joint-line improvement program undertaken by the ACRR, controlled by the Philadelphia & Reading Railroad, and the West Jersey & Seashore line (WJ&S), controlled by the Pennsylvania Railroad, for better service to southern New Jersey coastal points. The two lines shared a 25-year trackage right agreement that resulted in a new route over the Cape May Branch of the Atlantic City Railroad right-of-way to Winslow Junction, where WJ&S trains connected with the C&A main line for direct service to Camden and Philadelphia. Because of the high-speed connections needed between the ACRR and WJ&S as well as the Central Railroad of New Jersey (CNJ) at busy Winslow Junction, the junction was greatly improved, and several grade crossings between road and rail and two different rail lines were eliminated with overpasses. The Warren pony truss was built as part of the 1906 line improvement program that was completed in record time so as not to disrupt the lucrative summer business the ACRR enjoyed between Philadelphia and shore points. It carries a county road over the original right-of-way of the ACRR's Cape May Branch that was developed in the mid-1890s.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. Therefore, the boundary is the superstructure and substructure of the span itself. The rail line was not evaluated as a historic corridor.

SETTING / CONTEXT The bridge over a 2-lane road is located in a sparsely developed wooded and agricultural section and is surrounded by large tracts of pine barrens. The line was built in 1896 by the Atlantic City Railroad as a branch to Cape May from Winslow Junction. The line is one of several built during the second half of the 19th century to service the rapidly developing south Jersey shore.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single track riveted thru girder with floor beams and concrete abutments was built as part of a project undertaken by the Atlantic City Railroad to replace its original timber overpasses. This bridge is a representative example of the thru girder spans frequently used for rail overpasses in the area. Although built as part of a line improvement program and surviving in unaltered condition, the bridge is not technologically or historically distinguished.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The shallow built-up 3-span continuous thru girder with its original flooring system of stringers riveted to floor beams and wood decking (in-kind replacement) is a well-preserved example of an early overpass. It is supported on random ashlar abutments and steel bents on ashlar plinths. It is one of 4 similar overpasses built by the PA RR in lower Camden County between 1902-1905, and it is the best preserved of the four. The bridge is historically and technologically significant.

INFOR MATION

Bibliography:
Condit, Carl. American Building Art 19th Century. New York: Oxford University Press, 1960.

Physical Description: The narrow 3-span built-up thru girder bridge is supported on well-preserved rusticated ashlar abutments and steel columns on corresponding ashlar plinths. The flooring system is composed of stingers connected to the floor beams by riveted brackets and a plank wearing surface. The outside girders are shallow owing to the light capacity of the span. A modern beam guard rail has been added. The bridge crosses one active track.

Historical and Technological Significance: The 3-span overpass is one of a series of four built by the Pennsylvania Railroad in Camden County on its Atlantic City route between 1902 and 1905. The right-of-way was initially developed in 1854 by the Camden & Atlantic City Railroad which was absorbed by the Pennsylvania system in the early 1880s. This was the first line to service Atlantic City which became an extremely lucrative rail market. The Pennsylvania and Reading Railroads ran competing lines to Cape May and Atlantic City until 1933 when the two lines combined operations and created the Pennsylvania & Reading Seashore Line.

This span ranks as not only one of the oldest overpass bridges in the area but also one of the most complete. It is a well-preserved example of an early-20th century light-capacity built-up girder bridge. While thru girder bridges are common for both rail-over-road and road-over-rail spans, few survive with their original floor system preserved. Technologically the bridge is important as a record of the development of the built-up thru girder bridge type, easily one of the most popular bridges during the first half of the 20th century. The built-up girder bridge was developed for railroad use in 1846-47 for the Baltimore & Susquehanna Railroad, and, in time, it became the only serious competitor of the truss for railroad use.

SETTING / CONTEXT The bridge carries a local 2-lane street over one active track of the former Delaware River Railroad & Bridge Co. line built in 1896 from the Delair Bridge to the PA RR's main line in West Haddonfield. The residential area to the north is early 20th century while that to the south is post-WW II. Most of the overpass bridges on the short line are original structures.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span shallow thru girder overpass is supported on ashlar abutments and built-up steel bents on ashlar plinths. A welded column has been added to the center of each bent bay. The bridge retains its original floor system with I-section floor beams riveted to shallow built-up girders which support a plank deck. The wearing surface is asphalt. The iron railing is original. This is one of the two the best preserved of the 4 DRRR&B Co. overpasses in the county.

INFOR MATION

Bibliography:
Cook, W. George and William J. Coxey. Atlantic City Railroad. 1980.
Condit, Carl. American Building Art 19th Century. New York: Oxford University Press, 1960.
Gladulich, Richard. By Rail to the Boardwalk. Glendale, CA: Trans-Anglo Books, 1986.

Physical Description: The 3-span bridge is a shallow built-up multi girders supported on steel bents and ashlar abutments with wing walls. The bents, set on ashlar plinths, were originally toe-out angles joined by lacing. The bents have been strengthened by additional columns with batten plates rather than lacing. The flooring system composed of built-up floor beams carrying wood stringers carrying the plank wearing surface is an inkind replacement of the original wood elements. This is the only one of the four original DRRR & B Co. highway overpass bridges to retain its original flooring system. The sidewalk on both sides of the 2-lane roadway is enclosed by a wrought-iron fence-like railing that if not original to this bridge is original to those on the line. The sidewalks also have plank paving.

Historical and Technological Significance: The 3-span road-over-rail bridge is one of the best preserved of four surviving original overpasses built in 1896 as part of the original development of the Delaware River Railroad and Bridge Company (DRRR & B Co.) line that linked the 1896 Delran Bridge, the first railroad bridge over the Delaware River, with the existing rail lines in and around Camden. The DRRR & B Company was a wholly owned subsidiary of the Pennsylvania Railroad, and it built the bridge to expedite service on its lucrative route between Philadelphia and Atlantic City. The Pennsylvania Railroad developed the Delaware River Railroad and Bridge Company line as circumferential route to link the bridge with its existing lines in the area. The bridge was the first span to cross the river south of Trenton.

The DRRR & B Company line passed through congested residential areas which meant that rail and vehicular traffic would have to be separated. The railroad built the line between Pennsauken and Haddonfield in a manmade cut and carried vehicular roads over the cut on deck and thru plate girder bridges designed by and built at the expense of the Pennsylvania Railroad. Although the built-up plate girder developed in 1847, the Maple Avenue bridge in Pennsauken is a relatively early example of the bridge type in New Jersey. The deck and thru plate girders went on to become the only bridge type to compete with the steel truss for use on rail lines in the 20th century. This example, complete with its original type of flooring system that incorporates wood members, is an extremely well preserved example of this important bridge type. It is also significant for its historical association with the rail line and bridge that contributed directly to the development of both the Camden area and the southern counties of the state (criterion A, C).

Boundary Justification and Description: The bridge is evaluated as individually significant because it is a (1) well preserved example of a once-common bridge type and (2) a well-preserved artifact from the halcyon days of railroading in the area. While the surroundings have not maintained their integrity of setting, the bridge is complete. The boundary is thus limited to the span itself, the substructure and superstructure. 0466160 has also been evaluated as significant because there is no marked difference in the two spans.0466152

SETTING / CONTEXT The bridge crosses 1 track in a predominantly mid-20th century residential area with too many alterations to the houses to have historic district potential. There are also some commercial establishments. The Delaware River Railroad & Bridge Co. line was developed by the PA RR in 1896 to link the Delran bridge with the main line in West Haddonfield. It is now used by Amtrak.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Set on a substructure of ashlar abutments and built-up steel bents on ashlar plinths, the span is nearly identical to the other 4 DRRR&B Co. overpasses, but it appears that the deck has been raised so that the span is now a multi deck girder rather than a shallow thru girder bridge. The lattice railing is original. The span is a well-preserved example of its type and is thus historically and technologically significant reflecting the development of an important rail line and bridge type.

INFOR MATION

Bibliography:
Cook, W. George and William J. Coxey. Atlantic City Railroad. 1980.
Condit, Carl. American Building Art 19th Century. New York: Oxford University Press, 1960.
Gladulich, Richard. By Rail to the Boardwalk. Glendale, CA: Trans-Anglo Books, 1986.

Physical Description: The 3-span bridge is a shallow built-up multi girders supported on steel bents and ashlar abutments with wing walls. The bents, set on ashlar plinths, have laced channel legs and sway bracing. The bases of the columns are encased in concrete. The flooring system composed of built-up floor beams carrying a corrugated asphalt pan. The cantilevered plank sidewalk on both sides of the 2-lane roadway is enclosed by original handsome iron railing with a lattice web and cast square end posts and a molded hand rail. The original plans for the bridge survive.

Historical and Technological Significance: The 3-span road-over-rail bridge is one of the best preserved of four surviving original overpasses built in 1896 as part of the original development of the Delaware River Railroad and Bridge Company (DRRR & B Co.) line that linked the 1896 Delran Bridge, the first railroad bridge over the Delaware River, with the existing rail lines in and around Camden. The DRRR & B Company was a wholly owned subsidiary of the Pennsylvania Railroad, and it built the bridge to expedite service on its lucrative route between Philadelphia and Atlantic City. The Pennsylvania Railroad developed the Delaware River Railroad and Bridge Company line as circumferential route to link the bridge with its existing lines in the area. The bridge was the first span to cross the river south of Trenton.

The DRRR & B Company line passed through congested residential areas which meant that rail and vehicular traffic would have to be separated. The railroad built the line between Pennsauken and Haddonfield in a manmade cut and carried vehicular roads over the cut on deck and thru plate girder bridges designed by and built at the expense of the Pennsylvania Railroad. Although the built-up plate girder developed in 1847, the Maple Avenue bridge in Pennsauken is a relatively early example of the bridge type in New Jersey. The deck and thru plate girders went on to become the only bridge type to compete with the steel truss for use on rail lines in the 20th century. This example, complete with its original iron railings, is a well preserved example of this important bridge type. It is also significant for its historical association with the rail line and bridge that contributed directly to the development of both the Camden area and the southern counties of the state (criterion A, C).

Boundary Justification and Description: The bridge is evaluated as individually significant because it is a well-preserved example of a once-common bridge type is an artifact from the halcyon days of railroading in the area. The boundary is thus limited to the span itself, the substructure and superstructure. 0466152 has also been evaluated as significant because there is no marked difference in the two spans.

TOWNSHIP STONE HARBOR BOROUGH

TYPE SINGLE LEAF BASCULE **DESIGN** TRUNNION **MATERIAL** Steel

 # SPANS 32 **LENGTH** 1535 ft **WIDTH** 19.7 ft

CONSTRUCTION DT 1939 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT ASH, HOWARD, NEEDLES & TAMMEN **BUILDER** BETHLEHEM STEEL COMPANY

SETTING / CONTEXT The bridge carries two lanes of traffic and two sidewalks over a navigable channel south of Stone Harbor. North of the bridge are late-20th century summer residences. South of the bridge is a small undeveloped island and salt marshes. The bridge is privately-operated by the Cape May County Bridge Commission.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 32 span bridge has a 57' single-leaf haunched deck girder trunnion bascule main span and 31 deck girder and stringer approach spans. The bridge is finished with metal railings. It is one of 4 well preserved Ash Howard Needles & Tammen-designed bascule bridges built 1938-1940 on the Ocean Highway for the Cape May County Bridge Comm. with WPA funding. The group represents a major civic improvement, and all the bridges are historically and technologically distinguished.

INFOR MATION

Bibliography:
Brown, Kathi Ann. Design By Diversity. Kansas City, Missouri: The Lowell Press, 1989.
Cape May County Bridge Commission. Minutes 1934-1940.
New Jersey Laws, Session of 1910.
Seely, Bruce. Building the American Highway System. Philadelphia: Temple University Press, 1989.

Physical Description: The main span of the 32-span bridge is a 57'-long haunched deck girder with floor beams single-leaf trunnion bascule with a steel grid deck. The concrete counterweight is affixed to the underside of the tail end of the movable span. The approach spans are stringers and built-up deck girders supported on concrete pier bents with concrete cap beams for the stringers and braced concrete columns for the girders and movable leaf. A metal railing and safety sidewalks flank the roadway of the entire span. The cantilevered flat-roofed concrete Moderne-style operator's house on the inland side of the movable leaf is matched by a corresponding lookout with a bench on the ocean side. The bridge opens seasonally.

With the exception of the operator's control panel, which was placed in 1991, The operating mechanisms are primarily original or in kind replacements. The bridge operates by means of a pinion that engages a rack fixed to the outside of the girder near the trunnion. The enclosed primary and open secondary reducers and open drive gear sets are original as are the trunnions and supporting columns. The bridge is powered by an electrical motor. The machinery brake is original.

Historical and Technological Significance: The bridge over Great Channel is one of four nearly identical trunnion movable bridges designed by Ash Howard Needles & Tammen that were built under one contract for the Cape May County Bridge Commission in 1938-1940. The bridges were opened to the traveling public June 1940. The span is a well preserved representative example of what is the most common movable bridge type in the Jersey Shore region. Technologically it represents mid-1920s refinements in the important trunnion bascule bridge design developed in the early years of the 20th century. It is one of over a dozen of the same patented design built in the area between 1928 and 1940. Another was built on the Ocean Highway over Corsons Inlet for the Cape May Bridge Commission in 1947-48. Historically the bridges are monuments to the effectiveness of Depression-era New Deal programs to improve America's infrastructure (criteria A, C).

The Cape May County Bridge Commission was established by the county in 1934 for the purpose of having a means to apply for Federal Emergency Administration of Public Works funds to build movable bridges over navigable channels and two fixed bridges on the Ocean Highway in the county. A quasi-public commission, the original members were George N. Smith from Wildwood Crest, Luther C. Ogden, a former county Freeholder, of Cape May City, and G. W. Bergner, mayor of Avalon. The purpose of the commission was to "finance, construct, maintain, and operate self-liquidating toll bridges within the county." Having the private commission meant that the bridges could be constructed without cost to the county. Improving vehicular access to the Shore resort communities was viewed as a means of balancing the decline of train service to the tourist and seasonal-resident oriented area.

Ocean Highway was a route designation enacted by the 1910 New Jersey Senate and General Assembly (Chapter 220). The highway was to stretch from Atlantic Highlands in Monmouth County to Cape May City in Cape May County along, "as far as possible," improved existing roads near the ocean. The Commissioner of Public Roads was authorized to make route improvements where necessary with a $50,000. appropriation from the vehicle license fund. The improvements were made to the roadway over the next four years, but bridges were not a part of that work.

Ocean Highway was an element in the promotion of the Jersey Shore as a tourist and seasonal residence area. The route, which incorporates local and county streets, does not possess the integrity of setting nor technological significance to be evaluated as a potential historic district. It is merely a route designation that in Cape May County was promoted as the shortest route from Atlantic City to Cape May City.

The consulting engineer firm of Ash Howard Needles & Tammen (AHNT) from New York City played a pivotal role in the history of the bridge commission. By 1934, the firm, founded in Kansas City, Missouri in 1914 as the successor to one started by J.A.L. Waddell, had

established itself nationally as one of the leading designers of movable bridges, especially vertical lift bridges. Waddell was associated with the firm until he and John Harrington went their separate ways in 1914. The company opened its New City office in 1922 under the leadership of Harrington, Howard, and Ash. Work-relief program funded projects were an important source of work for AHNT, as it was for most engineering firms during the Depression, and the Cape May Ocean Highway bridges were a sustaining project for the New York office. The AHNT patent associated with the design of this particular bridge relates to the trunnion tower, and it was granted in 1926.

It was reported at the May 22, 1935 annual meeting of the Cape May County Bridge Commission that AHNT attended the meeting, and that they had prepared, on behalf of the commission, the actual application, complete with plans and specifications, to the Federal Administration of Public Works for $1,650,000 to build the Ocean Highway bridges. The application was not approved until June 14, 1938, at which time $744,545 was a grant and $910,000 was a loan. Work on the bridges began immediately.

The funding from the Federal Administration of Public Works met several objectives of various federal programs. It provided work for the unemployed. It was anticipated that between 350 and 500 local men would be put to work in addition to many "outside men," (CMCBC Minutes, 7/1/38). The bridges would improve traffic and focus on efficiency, as defined in engineering terms, which was a goal of the Bureau of Public Roads. Work relief-funded projects like the Cape May County Ocean Highway bridges kept the golden age of highway development alive during the Depression, when the lack of state and local funds would otherwise have stopped the effort (Seely, p. 88-91).

The four AHNT-designed movable bridges built on the Ocean Highway (3100003, 0500028, 3100005, 3100006) are all evaluated as significant because all are in a nearly complete state of preservation. The fact that they were built with funds made available through the federal government in an effort to create work is not sufficiently significant enough to meet National Register criteria because so many public works projects during the mid- to late-1930s were funded exactly the same way. The bridges were also not built with federally funded work crews such as the Civilian Conservation Corps (CCC).

Boundary Description and Justification: The bridge is evaluated as individually distinguished. While its immediate setting remains unchanged, the route of which it is a part does not possess the integrity or historical significance to be a potential historic district. Therefore, the bridge including the approach spans and structures related to its operation are evaluated as the limit of the historic resource. It is one of four movable bridges of similar design and date built under one contract for the Cape May County Bridge Commission.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 12-span continuous reinforced-concrete T-beam bridge has metal railings, concrete curbs, concrete bents with concrete caps, and concrete abutments. Several of the concrete piles have sheet metal or fiberglass jackets. The bridge is a representative example of a common type. It is historically associated with the WPA-funded Cape May County Bridge Comm. project that erected 2 fixed and 4 movable bridges 1938-1940. The route itself does not have historic district potential.

SETTING / CONTEXT The bridge carries two lanes of traffic over the Tuckahoe River, the border between Cape May and Atlantic Counties. The village of Tuckahoe, located south of the bridge on NJ 50, has several well-preserved buildings but has too many modern intrusions to merit historic district status. To the north are wetlands with a scattering of late-20th century residential development. The river's southern bank is lined with boat docks. The bridge opens to navigation with 24 hours notice.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The main span of the 3 span bridge is a single-leaf Strauss underneath articulated counterweight deck girder movable span flanked by encased deck girder approach spans. The bridge appears to survive in a good state of preservation with its original gear sets, gasoline engine, operator's house, locks, and safety gates. A steel grid deck was added in 1961. The bridge is a complete example of a historically and technologically significant patented movable bridge type.

INFOR MATION

Bibliography:
Hool & Kinne. Movable and Long Span Bridges. 1943. "J.B. Strauss Dies at Los Angeles." Engineering News-Record. 120 (May 19,1938). NJDOT: Bridge File: 0510152. Waddell, J.A.L. Bridge Engineering. 1925.

Physical Description: The main span of the 3-span 160'-long bridge is a single-leaf deck girder Strauss articulated underneath counterweight movable span. The approach spans are built-up deck girders. The substructure is concrete. With the exception of the replacement of the original gasoline engine with an electric motor (gasoline engine is the current auxiliary power source) and the steel grid deck placed in 1961, the bridge appears to survive in a nearly complete state of preservation. Both the movable leaf and the approach spans are enclosed by metal railings. The operator's house is located on a braced metal frame on the upstream outside of the movable leaf. It is a simple galvanized-metal clad gable-roofed structure. The interior was not inspected. The safety gates are original as are the manually activated toe locks.

The shafting, open gear sets, and racks and pinions appear to be original as does the gearing for manual operation. Because of the need to protect the electrical from water damage, the reduction of torque is accomplished through a series of shafts and bevel gear sets rather than straight shafts. This design is not uncommon when field conditions mandate that the power source be elevated to protect it. The trunnions are supported by built-up trunnion columns that bear on a concrete pier.

Historical and Technological Significance: The 1926 Strauss articulated underneath counterweight bridge over the Tuckahoe River is a complete example of the patented design that represents a milestone in the development of movable spans technology (criterion C). Although built near the end of the period of popularity of the design, the bridge documents the design that made J.B. Strauss (1869-1937) the most prominent engineer of movable span bridges in the early 20th century.

Strauss's patented bascule bridges were based upon an innovation on traditional bascule bridge construction. He reasoned if, unlike earlier bascule bridge designs that used a fixed counterweight and operated like a seesaw, he designed a bascule where the entire weight of the counterweight was concentrated at the tail end of the movable leaf, it would then be possible to use a lighter counterweight. Strauss was able to achieve this end through a linkage, or arms, that ensured that the counterweight moved in a series of parallel positions at all times when the span was in operation, and thus constantly maintained the position of the weight at the tail end of the leaf. Variations on the linkage could place the counterweight either overhead or underneath of the leaf. The design also held the advantage that less power was needed to start or stop the bascule's motion and the tail end was shorter thus reducing or eliminating the counterweight pit. In 1905 the first of Strauss's bridges was built in Cleveland, and in the same year he applied for a patent (995,813), granted in 1911. Strauss designed and marketed the immensely successful bridge through the Strauss Bascule Bridge Company of Chicago. Mainly through the efforts of Strauss, the bascule replaced the swing span bridge as the most popular movable span highway bridge type. In spite of the many movable bridges in this country for which Strauss was responsible, he is more often remembered as the chief engineer of the Golden Gate Bridge (1937) in San Francisco, California.

The technological significance of the NJ 50 over Tuckahoe River bridge is enhanced by its state of preservation and nearly complete original operating mechanical systems. It was built in 1926 on New Jersey Route 14, one of the original 15 state highway routes, and replaced a preexisting swing span bridge. The general contractor of the span was S. S. Thompson of Red Bank, Monmouth County, a company that was active in the construction of bridges throughout the state. When the electric motor was installed to replace the original gasoline engine is unknown. In 1961 a steel grid deck replaced original timber flooring. The bridge opens on 24 hours notice. In New Jersey there are at least eight other examples of Strauss bascule highway bridges including in Cape May County NJ 147 over Grassy Sound (0517151, Middle Township), a double leaf bascule with underneath counterweight constructed in 1922.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to the span itself, superstructure and substructure. The surrounding area does not have historic district potential.

DESIGNER/PATENT ASH, HOWARD, NEEDLES & TAMMEN **BUILDER** MERRITT, CHAPMAN & SCOTT

SETTING / CONTEXT The 4-lane wide bridge with one safety sidewalk spans Beach Thorofare, a navigable channel at the mouth of the Great Egg Harbor. The bridge is the southernmost span that is part of a causeway with 4 bridges (2 movable, 2 fixed) spanning between Somers Point on the north and Ocean City to the south. South of the bridge is a densely developed late-twentieth century summer residential community with marina.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 35-span bridge is composed of a single-leaf trunnion bascule main span and 32 reinforced-concrete T-beam approach spans. The 70'-long haunched deck girder with floor beams movable span has a fixed counterweight and metal railing. It was rehabilitated in 1988 with new enclosed primary reducer gears, electrical systems, controls, and a third story added to the operator's house. The bridge is an altered example of a locally common type, and the alterations reduce its technological significance.

SETTING / CONTEXT The 4-lane bridge with one safety sidewalk spans Ship Channel, a navigable channel at the mouth of the Great Egg Harbor River. The bridge is the northernmost of 4 bridges (2 movable, 2 fixed) that are part of a causeway between Ocean City to the south and Somers Point to the north. North of the Ship Channel bridge is the Somers Point traffic circle, and south of the bridge is an undeveloped island. The traffic circle is surrounded by modern commercial development.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Potential Somers Point Traffic Signal Historic District. May contribute.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 47-span bridge has a 50' single-leaf trunnion bascule main span, 8 deck girder spans, and 38 reinforced-concrete T-beam approach spans. The bascule is a haunched deck girder with floor beams and a fixed counterweight. The span was rehabilitated in 1988 with new electric systems and controls and a third story added to the concrete operator's house. Despite the updated equipment, the span retains most of its original fabric and is a technologically significant example of the bridge type. It is individually eligible for listing in the National Register of Historic Places under Criterion C. It may also be a contributing element of a Somers Point traffic circle historic district should such a district be identified in the future.

INFOR MATION

Bibliography:
Brown, Kathi Ann. Design by Diversity. Kansas City, Missouri: The Lowell Press, 1989; NJDOT. Bridge File: 0511153.

Physical Description: The main span of the 1442'-long bridge with a vertical profile is a single-leaf trunnion bascule with a clear span of 50'. There are 46 approach spans. The span immediately south of the bascule leaf is a haunched deck girder with floor beams that visually matches and balances the movable span. The other seven deck girder approach spans are composed of three deck girders with truss lateral bracing that are supported on braced concrete columns. The other approach spans are reinforced concrete T beams on concrete pile bents with cap beams. The entire bridge is enclosed by 2-rail high concrete railings except on the movable leaf which is finished with a metal balustrade-type railing. Concrete pylons inscribed with the date and route mark the approaches to the long bridge. Any original luminaries affixed to the pylons have been replaced by modern lighting.

The movable leaf is a haunched deck girder with floor beams and an open steel grid deck. It is a simple trunnion with a concrete counterweight set underneath the tail end. There is no counterweight pit. The span is operated by means of a rack and pinion drive activated by a series of reduction gears that transform the high rpm torque generated by the electric motors to the low rpm needed to lift the leaf. The open gear sets and other operating machinery appears to be original or in kind replacement. The electrical systems and controls, however, are modern, and were placed in 1988. At that time a third level was added to the operators house to improve visibility of the channel. The addition was designed to match the original styling of the structure. The windows and doors were also replaced in 1988. The signals and crash and safety barriers are new as well.

Historical and Technological Significance: NJ 52 over Ships Channel is one of six Ash Howard Needles & Tammen-designed standard or simple trunnion bridges in Cape May County, and it is technologically significant as a fairy well preserved example of its type. It still operates as originally designed, and it survives with its original or in kind replacement open sets of reduction gears, rack-and-pinion drives, and built-up deck girder leaf. As such, it is a good example of late-1920s and 1930s movable bridge technology (Criterion C).

The bridge design was successfully marketed by Ash Howard Needles & Tammen to counties, private bridge commissions, and the state after 1927, when members of the firm were issued a patent for an improved span support to resist the various stresses when the bridge is in operation as well as when it was at rest (#1,633,565). The standard trunnion bascule bridge had been in use since the early days of the 20th century, but the AHNT design came to the fore in New Jersey for locations on high piers or with a low water level after 1927. The need to cross active navigable bodies of water coupled with the boon in road improvement programs in the southern part of the state in response to increased traffic volume resulted in over a dozen of AHNT's movable bridges being erected in the four county Jersey Shore region between 1928 and 1948. Some of the popularity of the design may be attributable to the success of the firm's New York City office that was opened in 1922. Movable bridges that retain their original machinery arrangement are evaluated as significant because they are technologically distinguished engineering solutions to a complex problem.

Despite the 1988 modifications to the structure, such as the addition of a third floor to the operator's house and the removal of the original doors and windows, the span retains enough of its original fabric to maintain the integrity of original design.

Ash Howard Needles and Tammen, as the firm of Howard Needles Tammen and Bergendoff was styled in 1933, in large part made its early reputation as a nationally recognized consulting engineer firm through its movable span bridges, especially the vertical lift bridge. The firm's history goes back to 1892 when the noted engineer and author J.A.L. Waddell established his own consulting engineer firm at Kansas City, Missouri. Waddell was well known as the engineer of the 1893 South Halsted Street Bridge in Chicago, the first large-scale, high clearance vertical lift bridge in the country. Waddell was associated with several partners until 1914, when he and John Harrington dissolved the firm, divided the projects, many of which were vertical lift spans, and went their separate ways. Harrington took on new partners, and the firm was styled Harrington, Howard, and Ash. Henry C. Tammen was made a principal in 1928 as was Enoch R. Needles. The patent represented by the NJ 52 bridge was granted to Louis Ash, Henry Tammen, and Harry G. Hunter. The work of the firm is well represented throughout the country, and today it is one of the leading transportation planning concerns in the nation.

Boundary Description and Justification: The bridge, including the approach spans and substructure, is evaluated as individually significant. The boundary is thus limited to the right-of-way of the span itself.

SETTING / CONTEXT The bridge carries two lanes of traffic over Grassy Sound, a part of the Intercoastal Waterway. The area is a salt marsh and meadow with numerous seasonal homes on timber piles lining the highway. South of the bridge is a small marina and seafood restaurant. A new fixed high-rise bridge is being built approximately 500 feet south of the current movable bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Bridge was Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge is a haunched deck girder double-leaf Strauss bascule with 53 timber stringer approach spans. The 1922 bascule articulated underneath counterweights is the earliest surviving example of its type in the county, but it has some alterations. Much of the original fabric remains, including the operating equipment, but it is worn. The west leaf is a 1972 welded replacement of the original lost in an accident. It still remains a noteworthy example of an important and increasingly rare type.

INFOR MATION

Bibliography:
Hool & Kinne. Movable and Long Span Bridges. 1943; "J.B. Strauss Dies at Los Angeles." Engineering News-Record. 120 (May 19,1938); NJDOT: Bridge File: 0517151; Waddell, J.A.L. Bridge Engineering. 1925.

Physical Description: The main span of the 54-span 712'-long bridge is a 50'-span double-leaf haunched deck girder Strauss articulated underneath counterweight movable span. The trunnions are supported by built-up trunnion columns that bear on concrete piers. The approach spans, 38 to the east and 15 to the west of the main span, are timber stringers supported on timber pile bents. Both the movable leaves and the approach spans are enclosed by metal pipe railings. The operator's house is located on a braced metal frame on the northwesterly outside of the moveable leaf. It is a simple frame gable-roofed structure with composition siding. The shafting, open gear sets, racks and drive pinions, coffee grinder-type winched manual operation, and electric motors and controls appear to be original. Many elements are worn, and the concrete counterweight is deteriorating. There are no toe locks in use.

The bridge survives in a nearly complete state of preservation with the exception that in 1972 the original western built-up girder leaf with timber deck was replaced with one of welded construction with steel grid deck. The western leaf was lost in an accident when it opened beyond its limits. Other alterations include an extension to the operator's shanty and in 1979 the rebuilding of the eastern timber approach spans after fire damage.

Historical and Technological Significance: The 1922 Strauss articulated underneath counterweight bridge over Grassy Sound is a complete example of the patented design that represents a milestone in the development of movable spans technology (criterion C). Although built near the end of the period of popularity of the design, the bridge documents the design that made J.B. Strauss (1869-1937) the most prominent engineer of movable span bridges in the early 20th century.

Strauss's patented bascule bridges were based upon an innovation on traditional bascule bridge construction. He reasoned if, unlike earlier bascule bridge designs that used a fixed counterweight and operated like a seesaw, he designed a bascule where the entire weight of the counterweight was concentrated at the tail end of the movable leaf, it would then be possible to use a lighter counterweight. Strauss was able to achieve this end through a linkage, or arms, that ensured that the counterweight moved in a series of parallel positions at all times when the span was in operation, and thus constantly maintained the position of the weight at the tail end of the leaf. Variations on the linkage could place the counterweight either overhead or underneath of the leaf. The design also held the advantage that less power was needed to start or stop the bascule's motion and the tail end was shorter thus reducing or eliminating the counterweight pit. In 1905 the first of Strauss's bridges was built in Cleveland, and in the same year he applied for a patent (995,813), granted in 1911. Strauss designed and marketed the immensely successful bridge through the Strauss Bascule Bridge Company of Chicago. Mainly through the efforts of Strauss, the bascule replaced the swing span bridge as the most popular movable span highway bridge type. In spite of the many movable bridges in this country for which Strauss was responsible, he is more often remembered as the chief engineer of the Golden Gate Bridge (1937) in San Francisco, California.

The technological significance of the NJ 147 over Grassy Sound bridge is enhanced by its state of preservation and nearly complete original operating mechanical systems. It was built in 1922 for the county, and jurisdiction was transferred to the state in 1970 when the road became part of the state highway system. In New Jersey there are at least eight other examples of Strauss bascule highway bridges including in Cape May County NJ 50 over the Tuckahoe River (0510152, Upper Township), a single leaf bascule with underneath counterweight constructed in 1926.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to the span itself, superstructure and substructure. Upstream from the bridge is the HPO's identified potential historic district of Grassy Sound that developed along the old railroad right-of-way. The potential district has not been finalized.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Originally a single-span, the bridge has been significantly altered by the addition of timber-piling piers that make it a three-span bridge, by concrete reinforcing of the stone abutments and wing walls, by the addition of a second steel I-beam on top of the original stringers, and by the addition of a steel guide rail. The bridge is an older example of a common bridge type, but due to alterations it is not historically or technologically distinguished.

SETTING / CONTEXT The two-lane wide bridge spans the Maurice River on the Salem and Cumberland County border. On the Cumberland County side of the bridge is Vineland City's West Side Park (c. 1980), a municipal picnic area and beach. On the Salem County side is the state's Union Lake Wildlife Management Area with new-growth forest and dense undergrowth. Downstream from the bridge is a small concrete dam.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span, steel stringer bridge has concrete-encased fascia stringers, reinforced-concrete substructure, balustrade, and sidewalks. Approximately one-third of all the pre-1946 bridges in Cumberland County are steel stringers. The bridge has a design similar to many bridges designed and built by county engineers' offices in the 1920s and 1930s. Contractors from Mount Holly, NJ, built the bridge. It is not historically or technologically distinguished.

DESIGNER/PATENT WALTER M. SHARP, CO. ENG. **BUILDER**

SETTING / CONTEXT The two-lane, 11-span culvert and dam is located at the northeast corner of Bridgeton City Park (c. 1900-20). Sunset Lake, above the dam, is used for boating and fishing, and is one of the park's central features. To the east is a residential development (c. 1920-60). The lake and dam were originally a part of the waterpower system of the Cumberland Nail and Iron Co. In 1903, Bridgeton purchased the land for a city park.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The roadway is carried on an 11-span concrete box culvert that is an earth-filled dam/spillway. The well-preserved bridge/dam has a concrete headwall with balustrade and is a siphon spillway design, drawing water off the bottom of the lake through a series of siphon-shaped inlets. The dam was built in 1938 after a previous dam collapsed in a 1934 flood. Inverted siphons are not a common structural type, and thus it is eligible because of its technological significance.

INFOR MATION

SOURCES:
Cumberland County Engineer Records. File Cards. Bridge No. 0600018, CR 621, MM 2.35.
Logue, William A. "Parks." Bridgeton History. 1936.
"Sunset Residents Unhappy, June 21, 1977." Vertical File. Bridgeton Public Library, Bridgeton, NJ.
Williams, George Bansby. Storage Reservoirs. London: Chapman and Hall, 1937.

PHYSICAL DESCRIPTION: The dam and bridge is a design known as a siphon spillway. The spillway draws water off the bottom of the lake through a series of siphon-shaped inlets and discharges the water downstream through the eleven reinforced-concrete box culverts. The dam is earth-filled with a concrete headwall with pierced balustrade. The spillway has not been significantly altered, although newspaper records indicate that at some time past a flow box was added to the bridge to provide for enough surface current to remove scum and stagnant surface water near the dam.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The bridge/dam, located in Bridgeton City Park, is a well-preserved example of an uncommon structural type. Dams with siphon spillways came into general use in the United States and Europe in about 1905, but were not a frequently used type. It appears that in this application the type was selected so that the structure could perform two functions; (1) serve as the superstructure for the roadway over the dam and (2) control the water level to a create a small lake which is a feature in the park and a source of fresh water. No other inverted siphon dam bridges have been identified in southern New Jersey.

The dam and lake in Bridgeton City Park were originally a part of the waterpower system of the Cumberland Nail and Iron Company. In the early 1900s the foundry and factory went into bankruptcy and in 1903 Bridgeton City bought the lake and the surrounding land with the intention of maintaining it as a public playground and park. In 1934, the old dam constructed by the Cumberland Nail and Iron Company went out in a flood. In 1938, the county completed construction of the present dam, bridge, and spillway.

CONSTRUCTION DT 1936 **ALTERATION DT** 1978 **SOURCE** COUNTY ENGINEER

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The two-lane wide bridge spans a small creek in a low-lying marsh with a dead-tree stand. Nearby are a sandpit, a commercial warehouse, and ranch homes (c. 1960-1980).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 11/22/91

SUMMARY The bridge is one of at least four existing, short-span, steel-stringer bridges with timber-pile bents and abutments built by Cumberland County between 1930 and 1942. In 1978 the county replaced the timber piles, deck and railing. The bridge has timber fascia stringers that support the beam guide rail. Little original bridge fabric remains. Steel stringers are the most common pre-1946 bridge type in New Jersey. The bridge is not historically or technologically distinguished.

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The two-lane bridge spans a tidal estuary of the Maurice River south of Millville. Next to the bridge is a heavily altered two-story frame house (c. 1870). The surrounding area is rural with fallow fields and scrub brush. Downstream are the remains of an old stone abutment, probably the site of an earlier bridge. Rotted timber pilings, piers, and wharfs suggest a once active maritime community.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bobtail thru girder with floor beams swing span bridge with a steel stringer approach span has concrete abutments and piers. Electrical service has been removed from the swing span, and it was sealed to navigation in c.1968. Encasing has been removed from the fascia stringer of the approach span. The bridge is the least well-preserved and historically-documented of two similar 1920s swing spans in the region (1708151). The other swing span is recommended eligible.

INFORMATION

SOURCES:
Hool, George A. and W. S. Kinne. Movable and Long-Span Steel Bridges. New York: McGraw Hill, 1923.
New Jersey State Highway Department Bridge Division. Bridge Plans File No. 0601152. 1925.
Waddell, J. A. L. Bridge Engineering. New York: John Wiley & Sons, 1916.

PHYSICAL DESCRIPTION: The bridge is a center-bearing, bobtail, riveted thru girder swing span with an encased stringer approach span to the south. The swing span superstructure consists of two riveted plate girders, floor beams and stringers, lateral bracing, and steel-grid deck. A concrete counterweight supported in a steel framework is underneath the deck on the shorter, bobtail end of the span. Above the center pier is a box-shaped cross girder designed to support and balance bridge upon the center bearing when in the open position. Four balance wheels are attached to the cross girder and floor-beam system and roll on a circular track mounted on the center pier. The bridge was operated by a single pinion turning against a rack of approximately 10'-radius. A set of six wedges, two at each end of the bridge and two at the center pier, lifted the end of the bridge in the closed position. The rack and pinion and wedges were operated by an electric motor and a system of direct-drive line shafting and beveled gears, all of which are extant. The operator's shanty and all electrical service and controls have, however, been removed. The bobtail swing span has an overall length of 89' with a 30' roadway.

The 51'-long, steel-stringer approach span is concrete-encased with balustrades. The concrete encasing has been removed from the fascia stringers. The abutments and piers are reinforced-concrete founded on timber piles. Repairs have been made to the piers with new concrete caps underneath the wedge lifts. The center pier is badly spalled. The bridge has timber-pile fenders. Since 1968, it has been closed to navigation, and traffic control equipment has been removed.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The swing span bridge is 1 of 2 nearly-identical swing spans designed in the mid-1920s by the NJ State Highway Department for state highways in South Jersey. The other bridge (1708151), NJ 49 over Alloways Creek in Quinton, Salem County, is the better preserved and documented of the two bridges, and has been recommended eligible as a rare surviving example of a technologically significant movable bridge type.

The swing span is a type of movable bridge, a special structural type combining both civil and mechanical engineering technologies. Swing spans were one of the most prevalent types of movable bridges during the 19th and early-20th centuries. The NJ 47 over Manantico Creek Bridge is a late example of movable-bridge technology employing girder superstructure, wedge end lifts, and electrification, all of which were improvements in swing span design during the period between 1890 and 1920. Constructed in 1925, the bridge was built as part of the NJ State Highway Route 15 improvements. It replaced a bobtail truss swing span that once stood slightly downstream from the existing bridge. No documentation has been located to identify the builder.

SETTING / CONTEXT The four-lane bridge spans a tidal estuary of the Delaware Bay in the center of downtown Bridgeton, a once thriving maritime community and industrial center. On the river's east bank is a diner (c. 1930) and a river walk development (c. 1980). On the west bank is a closed textile mill (c. 1890) and commercial buildings (c. 1870-1990). The bridge lies within the Bridgeton Historic District.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Bridgeton Historic District. 08/18/1982. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The War Memorial Bridge is a 2-span, single-leaf trunnion bascule that was sealed about 1969. Some controls were removed at that time, but the drive mechanism remains. It was constructed in 1936 and is outside the Bridgeton Historic District's period of significance (c. 1790-1900). One of over 12 examples of the design in southern New Jersey, the bridge is not significant due to alterations. More complete examples survive.

INFOR MATION

SOURCES:
Cushing, Thomas, and Charles E. Sheppard, eds. History of the Counties of Gloucester, Salem, and Cumberland, New Jersey. Philadelphia: Everts & Peck, 1883.
Hool, George A. and W. S. Kinne. Editors. Movable and Long-Span Steel Bridges. New York: McGraw-Hill, 1923.
New Jersey Department of Transportation. Bridge Files and Plans, 0604152, 1935.
Waddell, J. A. L. Bridge Engineering. New York: John Wiley, 1916.

PHYSICAL DESCRIPTION: The western span of the two-span bridge is a non-operative single-leaf trunnion bascule of the underneath counterweight type. The eastern span, although similar to the northern span in outward appearance, is a fixed, segmental-shape deck plate girder. Overall the bridge is 156'-long with 40'-roadway.

The western bascule span is constructed of two girders that span a distance of 72' from toe bearing to trunnion. The girders are tapered from approximately 9' depth at the trunnion to 4' depth at the center of the span, to 6'6" depth at the toe. In addition, there are steel angle cross braces which act as stiffening members for the bascule span. Floor beams frame into the girders at approximately 14' intervals. The floor beams support steel stringers and a steel grid deck with asphalt roadway. Two 8' wide sidewalks with steel balustrades are supported by steel brackets on either side of the span.

The counterweight and operating machinery are concealed in a watertight pit below the roadway at the northern end of the bridge. The counterweight is concrete in a steel frame attached to the short arm of the bascule girders. The bascule leaf is opened by pinion gears engaging cast-steel racks of 7'6" radius about the trunnions of either girder. The pinion gears are operated by a single electric motor attached to trunnion shafts and gears. The bridge also has a motor brake and a speed change for hand operation.

The movable span provides navigational clearance of 40' with a minimum vertical clearance of 6' at mean high water. The bridge has timber pile fenders. A one-story concrete operator's house with concrete-slab hipped roof stands next to the bascule on the southwest corner.

The eastern span is a 72'-long plate girder. The two girders are made of web plates and angles and taper from 6'8" depth at the toes to 4' depth at the center of the span. Floor beams frame into the girders and there are steel cross braces which act as stiffening members. The floor beams support steel stringers and a concrete slab deck.

The bridge foundations are reinforced concrete and consist of two abutment and a pier.

HISTORY AND SIGNIFICANCE: The Broad Street Bridge is an example of a technologically significant bridge type that is becoming increasingly rare in New Jersey and the United States. The bridge is the best preserved, and perhaps the only, bascule highway bridge of the underneath counterweight type remaining in the state. Constructed in 1935-36, it utilizes details found on most other simple trunnion bascule bridges of the underneath counterweight type. The bridge is a local landmark on one of the primary highway routes in Bridgeton, and is dedicated as a memorial to the veterans of WWI. It is within the boundaries of the Bridgeton Historic District but was not built during the district's period of significance (ca. 1790-1900).

The bascule is a type of movable bridge, a special structural type combining both civil and mechanical engineering technologies. They are erected where navigation demands vertical clearance and the surrounding landscape does not permit elevated approaches. Thus, they are commonly found in low lying coastal areas, like South Jersey. The modern type of bascule bridge developed in the United States during the 1890s in Chicago. The most prevalent patented types of bascule bridges were the Scherzer and Rall rolling lift bridge, the Chicago City, and the Strauss Trunnion Bascule types. Construction of bascule highway bridges probably reached a peak in the period between 1900 and 1930. The Broad Street Bridge is an example of the simple trunnion type and does not make use of the Strauss patented features.

Since 1869 a bridge has spanned the Cohansey River at the present site. The previous bridge was a wrought-iron swing span, 135'-long

A. G. Lichtenstein & Associates, Inc. performed initial survery.

Correspondence.Unit@DOT.State.NJ.US
November 12, 2002

and 30'-wide, with arms of equal length. In 1934 a flood destroyed the old swing span. The New Jersey State Highway Department undertook to rebuild the bridge and chose the engineering firm of Ash, Howard, Needles, and Tammen of New York and Kansas City to prepare the bridge designs and specifications. The general contractors for the bridge were Merritt-Chapman and McClean Corporation of Baltimore, Maryland.

Bridgeton, the furthest navigable point on the Cohansey River, was once a thriving maritime city with regular ferry service to Philadelphia and New York City, glass factories, and a nail works. The maritime economy declined in the first part of the 20th century. In the mid-1960 it was determined to close the bridge to river navigation.

CONSTRUCTION DT 1904 **ALTERATION DT** 1951 **SOURCE** INSCRIPTION/PLANS

DESIGNER/PATENT ESSEX COUNTY PARK COMMISSION **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 4-lane divided road over a 2-lane park road set in Branch Brook Park, one of the original parks in the country's first county park system. The Essex County Park Commission, established in 1895, began the park development in 1896. Designed by nationally prominent landscape architects the Olmsted Brothers, the park is listed in the National Register. The bridge dates to the development of the middle division of the park where it is located.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Branch Brook Park. 01/12/1981. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The elliptical reinforced concrete arch bridge supported on a concrete substructure was widened in kind to the north in 1951. Panelled parapets flank the concrete sidewalks. Raised concrete circular seals decorate the spandrel walls. A long and well-detailed example of its type, the span was constructed in the period of significance of Branch Brook Park. The span is one of 7 arch spans in the park, and it is a prominent and original park feature.

INFOR MATION

Bibliography:
Essex County Engineers Office.
ONJH National Register File: Essex County, Branch Brook Park, Newark, New Jersey.
Report of the Essex County Park Commission, 1901.

Physical Description: The elliptical reinforced concrete bridge spans 69'-8 1/4", and carries a 4-lane median divided county road and sidewalks over a park road with sidewalks. The bridge was widened in kind by 34' to the north in 1951. The panelled concrete parapets, the concrete median and sidewalks date to the widening. The original face of the spandrel walls has a raised concrete seal with the date of construction inscribed.

Historical and Technological Significance: The reinforced concrete deck arch bridge, constructed in 1904, is technologically significant because it is a relatively long and well-preserved concrete arch span, and it is historically distinguished because it is one of 4 arch bridges constructed between 1898 and 1930 as part of the development of the National Register-listed Branch Brook Historic District that consists of a Olmsted-designed park that is the centerpiece of the nation's first county park system. It is one of a total of seven significant arch spans located in Branch Brook Park (Criteria A and C).

The bridge was built for the Essex County Park Commission as part of the development of Branch Brook Park in Newark. The park is one of the original parks developed as part of the nation's first county park system. The Essex County Park Commission was formed in 1895, and they began plans for the development of two major parks, two reservations, and four smaller parks. Branch Brook Park was the most important and extensively developed of the original parks. The park was sectioned into three divisions. The southern division was the first section of the park to be developed, and construction began in 1896. John Bogart and N.F. Barrett, Landscape Architects and Engineers, provided the initial plans for the southern division. They were terminated in 1897 due to cut backs in funds.

In 1898, the Olmsted Brothers firm was hired, and they apparently revised Bogart & Barrett plans for the completion of the southern division and also developed plans for the middle and northern divisions. The Olmsted Brothers firm was established by Frederick Law Olmsted, Sr. (1822-1903) who is considered the founder of landscape architecture as a profession in this country. In 1857, he designed Central Park in New York, and he and/or his firm were responsible for many other noted landscape works in the country, such as the National Zoo in Washington, D.C., the United States Military Academy at West Point, the Capital Grounds in Washington, D.C., and the campuses at Harvard, Yale, Stanford universities and Amherst College, among others.

The southern division of Branch Brook Park was designed to be comparatively ornate. The northern division was designed to have a natural rustic style, and the middle division was designed to have an intermediate style transitioning between the other divisions. The span is located between the southern and middle divisions, and it was constructed to eliminate a grade crossing of a busy road with the park road, and to allow easy access between two park divisions. The bridge was designed to be simple in style in keeping to the less elaborate character of its surroundings.

Boundary Description and Justification: The bridge is located within a National Register-listed historic district. As a contributing resource to that district, both the span and its surroundings are evaluated as significant. For a detailed boundary description, refer to the National Register file at ONJH.

SETTING / CONTEXT The bridge carries a 2-lane collector road with a turn-lane and sidewalks over a small stream adjacent to a town park and located between an area of post-WW II commercial structures and a neighborhood of single-family homes dating from the 1920s.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stone barrel arch bridge of coursed ashlar and finished with ringstones was widened on the upstream side with a reinforced concrete slab in 1931. A metal railing flanks the sidewalk at the downstream side, and a plain concrete parapet dating to the 1931 widening flanks the upstream sidewalk. As well, concrete scour protection has been added. One of over 7 stone arch bridges in the county, the span is not distinguished because its visual integrity has been compromised by alterations.

SETTING / CONTEXT The bridge carries a 4-lane collector road and sidewalks over a small stream in a town center adjacent to a county park. The commercial buildings in the area date from the 1890s to the present. Verona Park, now part of the Essex County Park system, was the center of activity for a thriving resort town in the mid 1800s.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stone barrel arch bridge is of coursed ashlar and finished with ringstones. It was widened in 1900. In 1945 a freshet damaged the downstream side, and it was repaired and widened with encased stringers supported on concrete abutment extensions. A concrete balustrade was placed at one side and the original masonry parapet remains at the other. One of over 7 stone arch spans in the county, the bridge is not distinguished because of its loss of integrity.

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a shallow stream adjacent to a county park and a residential area dating from the 1910s to the 1920s. Yanticaw Park, to the north of the bridge, was designed by the Olmsted firm.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The brick deck arch bridge with ashlar spandrel walls springs from ashlar subabutments. In 1929 reinforced concrete wingwalls were added, and the span was widened at the south to accommodate a concrete sidewalk. In 1965 the north spandrel wall failed and was repaired with a concrete backup wall. Scored concrete facing was added to the parapets. The span predates the Olmsted park, and its numerous alterations and condition of the brick arch mar its historical and technological significance.

SETTING / CONTEXT The bridge carries a 2-lane city street over a small stream in a mixed-use urban community of altered multi-story commercial and residential buildings dating to the early 1900s. The Public Service Company of NJ's Orange electric sub station is located at the south east corner. The original brick building was constructed in 1900ca, and additions at the site date through the 1960s.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The short rolled stringer and brick jack arch bridge supported on ashlar abutments has metal railings flanking the sidewalks. Records state that the stringers are iron. In 1975 a shallow rolled stringer was welded to the bottom flange of 4 stringers. The bridge is a common type from the 1880s through the 1910s, and it is not technologically or historically distinguished. 0700088 and 0700065 are significant examples of the type, and each is located within a historic district.

INFOR MATION

Bibliography:
Essex County Engineers Office, (file 7-A-8A)
Essex County Board of Chosen Freeholders Minutes, 1886-1887.

Physical Description: The single span stringer with brick jack arch bridge is supported on cut stone masonry abutments that are continuous with concrete retaining walls along the stream channel. The Freeholders Minutes state that the span is to be built with iron stringers. The bridge spans 22', and it measures 39.5' wide curb-to-curb and 64' wide out-to-out. The bridge carries 2 sidewalks and it is flanked by metal picket railings. In 1975 the fascia and 1st interior stringers were strengthened at both sides of the bridge. W6 x 16 beams were added under the existing interior stringers and tie rods were welded to the fascia stringers. No plans were located.

Historical and Technological Significance: The 1887 stringer and brick jack arch bridge, reportedly built with iron stringers, is an example of a bridge type that was common for short spans in north eastern New Jersey in the late 1800s. In the 1890s the bridge type continued to be constructed but steel beams were used in place of iron. By 1910, with the development of the concrete deck, brick jack arch decks were no longer being used. The Essex County Freeholders Minutes for the year 1886-1887 indicates the masonry construction was performed by E. J. Coddington, and the iron work was performed by Albert Smith, both being local contractors. The span is one of only two known extant stringer bridges built with iron stringers that are documented as such in the county, and it is the better preserved example. It is thus significant as a rare and early example of what was once a common bridge type (Criterion C).

Boundary Description and Justification: It is the bridge and not its setting that are evaluated as significant. Therefore, the boundary is limited to the span (substructure and superstructure) itself.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 4-lane one-way collector road and sidewalks over a minor stream in the center of town adjacent to a town park. The span is located in a commercial area dating from the turn-of-the century to the 1920s.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-span masonry deck arch bridge has ashlar parapets with granite capping stones. The 2-easternmost spans have been widened by 5' at the north side of the bridge to accommodate a cantilevered slab extension of the sidewalk. Gunite was applied to the intrados in 1975. An example of an early bridge type that has undergone only minor alterations, the span retains much of its original fabric, and it is a significant local example of the type.

INFOR MATION

Bibliography:
Essex County Engineers Office. Beginnings 1700-1800 The Colonial History and Architecture of Millburn, New Jersey.
Essex County Board of Chosen Freeholders Minutes.

Physical Description: The 4-span stone arch bridge is constructed of coursed ashlar masonry. Spanning 69' and measuring 50' wide, the bridge carries a 4- lane road flanked by concrete sidewalks and ashlar parapets with granite cap stones. The two easternmost spans were widened by 5' at the north side of the bridge to accommodate a cantilevered extension of the sidewalk. The modification is not intrusive. This was done to provide access to the building at that corner. In 1975, gunite was applied to the inside of the arch intrados, and the span was repointed. No other alterations to the span were noted. Plans were not located.

Historical and Technological Significance: The 1869 span is significant because it is the longest multi-span and one of the oldest stone arch bridge in the county, and it retains much of its original styling (Criterion C). The coursed ashlar stonework is typical of the 1868-1880 period in Essex County. Of the seven stone arch bridges identified in county as having been built between 1868 and ca. 1875, two are located in National Register-listed Branch Brook Park in Newark and are evaluated as contributing resources (0700068, 0700036), and the other four are not as complete as this example.

Located in the town center of Millburn, most of the buildings in the immediate area date to the late 1800s and early 1900s, and therefore its historic context has not been compromised. Because of the alterations to most of those buildings, however, the area does not appear to have the architectural integrity to be evaluated as a potential historic district. Historically, a span has crossed this location since before the Revolution. During the Revolution, the bridge at this crossing, named the Egbeson's Bridge, was a strategic site during the 1780 Battle of Springfield.

Boundary Description and Justification: Since the bridge is evaluated as individually distinguished, the significant boundary includes both the span itself and the slab addition added in 1955. It does not include the surrounding buildings, most of which are altered.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete deck arch bridge supported on a concrete substructure has standard-design concrete balustrades. One of over 9 concrete deck arch bridges in the county, the span is a representative example of its type, but it is located in a National Register-listed district. A major element in the park design, it is a contributing resource that helps establish the character of the area. It is one of 7 bridges in the park.

INFOR MATION

Bibliography:
Essex County Parks Department (Plans)., ONJH National Register Files: Essex County, Branch Brook Park, Newark, New Jersey. The Running Brooks and Other Sketches of Early Newark, by Edward S. Rankin, C.E., The Unionist-Gazette, Somerville, NJ, 1930.

Physical Description: The elliptical reinforced concrete arch bridge carries a 2-lane road over a small river in a county park. The bridge spans 49' and measures 40' curb-to-curb. The arch has an 11' rise. Concrete sidewalks are flanked by standard-design concrete balustrades. The span appears unaltered.

Historical and Technological Significance: The 1918 reinforced concrete arch bridge is a representative example of its type, and individually it is not distinguished. However, it is located within the national Register-listed Branch Brook Park and it is a major element in the park design, and it is a contributing resource that helps establish the character of the area. It is one of 7 significant arch bridges in the park. (Criterion C).

Branch Brook Park is one of the original parks developed as part of the nation's first county park system. The Essex County Park Commission was formed in 1895, and they began plans for the development of two major parks, two reservations and four smaller parks. Branch Brook Park was the most important and extensively developed of the original parks. The park was sectioned into three divisions, the southern, middle and northern divisions, and John Bogart and N.F. Barrett, Landscape Architects and Engineers, provided the initial plans for the southern division of the park. They were terminated in 1897 due to cut backs in funds. In 1898, the Olmsted Brothers firm was hired, and they designed general plans for the completion of the southern division and new plans for the other divisions. The Olmsted Brothers firm was established by Frederick Law Olmsted, Sr. who is considered the founder of landscape architecture as a profession in this country. In 1857, he designed Central Park in New York, and he is responsible for many other noted landscape works in the country, such as the National Zoo in Washington, D.C., the United States Military Academy at West Point, the Capital Grounds in Washington, D.C., and the campuses of Harvard, Yale, and Stanford universities and Amherst College, among others.

In the mid-1920s the land along the Second River between Newark and Belleville occupied by Hendricks Copper Mills and which included this span was acquired by the Essex County Park Commission in order to extend Branch Brook Park. In 1927 Caroline Bamberger-Fuld donated over 2000 Japanese Cherry Blossom trees to the Essex County Park Commission, and the trees were planted in the park extension along the Second River. The Essex County Park Commission has added to the collection through the years and it is now the largest display and variety of such trees in the United States attracting visitors from all over the country during the spring season.

Boundary Description and Justification: The bridge is located within a National Register-listed historic district. As a contributing resource to that district, both the span and its surroundings are evaluated as significant. For a detailed boundary description, refer to the National Register file at ONJH.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The coursed ashlar 3-span stone arch bridge is detailed with voussoirs. The corresponding parapets have granite cap stones and metal railings. Undermining at the foundations has been repaired with concrete. The bridge is significant because it is a well-preserved and early example of a multi-span stone arch bridge. It predates the establishment of Branch Brook Park, but it contributes to its picturesque character. The span is individually significant and it contributes to the historic district.

INFOR MATION

Bibliography:
Essex County Engineers Office.
Essex County Board of Chosen Freeholders Minutes.
ONJH National Register File: Essex County, Branch Brook Park, Newark, New Jersey.

Physical Description: The 3-span stone arch bridge is built of rusticated coursed ashlar masonry and finished voussoirs and a keystone. Spanning 73' and measuring almost 60' wide, the bridge carries a 4-lane road flanked by concrete sidewalks and ashlar parapets with granite cap stones. A stone at the center of the east parapet is inscribed with the date, the names of the contractors and the names of the county freeholders. County records indicate that the bridge originally constructed in 1868 was shorter, but it caused flooding problems and damage to a local business. The bridge was lengthened in 1869 to alleviate this problem. A concrete invert slab was added, and the masonry was repointed at an unknown date. No other alterations to the span were noted. Plans were not located.

Historical and Technological Significance: The 1868-1869 3-span stone arch bridge is technologically significant because it is the earliest example of a multi span stone arch bridge in the county. Additionally, it is located in the extension division of Branch Brook Park, a National Register-listed historic district. The bridge contributes to the historic character of the park. It is one of seven significant arch spans in Branch Brook Park (Criteria A and C).

The bridge was constructed in 1868 by N.B. Adams and V.M. Parsons, local contractors, and it predates the park. The span is located at the terminus of the extension division of Branch Brook Park, one of the original parks established by the Essex County Park Commission as part of the development of the nation's first county park system. The Essex County Park Commission was formed in 1895, and they began plans for the development of two major parks, two reservations and four smaller parks. Branch Brook Park was the most important and extensively developed of the original parks. The park was divided into three divisions, the southern division was the first section of the park to be developed and construction began in 1896. John Bogart and N.F. Barrett, Landscape Architects and Engineers, provided the initial plans for the southern division of the park. They were terminated in 1897 due to cut backs in funds. In 1898, the Olmsted Brothers firm was hired, and they designed general plans for the completion of the southern division and new plans for the middle and northern divisions. The Olmsted Brothers firm was established by Frederick Law Olmsted, Sr. who is considered the founder of landscape architecture as a profession in this country. In 1857, he designed Central Park in New York, and he is responsible for many other noted landscape works in the country, such as the National Zoo in Washington, D.C., the United States Military Academy at West Point, the Capital Grounds in Washington, D.C., and the campuses of Harvard, Yale, Amherst, and Stanford.

In the mid-1920s the land along the Second River between Newark and Belleville occupied by Hendricks Copper Mills, and which included this bridge, was acquired by the Essex County Park Commission in order to extend Branch Brook Park. In 1927 Caroline Bamberger-Fuld donated over 2000 Japanese Cherry Blossom trees to the Essex County Park Commission to be planted in Branch Brook Park, and the trees were planted in the park extension along the Second River. The Essex County Park Commission has added to the collection through the years and it is now the largest display and variety of such trees in the United States attracting visitors from all over the country during the spring blooming season.

Boundary Description & Justification: The bridge is located on the northeast boundary of the Branch Brook Park Historic District. It appears from the verbal boundary description that the entire span (both elevations) is within the nominated acreage, but only the land adjacent to the west elevation is included. Thus the land adjacent to the east elevation is not evaluated as significant or contributing. For a more complete description of the district's boundaries, refer to the National Register files at ONJH.

CONSTRUCTION DT 1900ca **ALTERATION DT** 1940ca **SOURCE** STYLE

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a 2-lane city street with sidewalks over a minor stream in an urban neighborhood of apartments constructed in the 1960s and houses dating to the 1920s. A brick storm sewer empties into the stream at one side of the bridge. The west elevation is hidden by a covered culvert. A building once stood where the channelized stream is. It is now an undeveloped lot.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The built-up multi girder and brick jack arch bridge is supported on ashlar abutments. A metal railing flanks the east sidewalk. The west elevation is hidden by a culvert that connects this span to 0700075 (500' to the west). Two of the jack arch bays have been replaced with concrete slabs. A brick storm sewer that has been strengthened with gunite is located through a wingwall. The altered span is not well preserved, and it is neither historically nor technologically distinguished.

INFOR MATION

Bibliography:
Essex County Engineers Office.

Physical Description: The single span multi-girder with brick jack arches bridge is supported on an ashlar substructure. The riveted girders are composed of two pairs of angles and a web plate. The bridge measures]' in length and carries a 36' wide road and two 12' sidewalks. Concrete encased utilities have been added and two of the jack arch bays have been replaced with concrete slabs. The original decorative metal railing remains at the east fascia. The west fascia is not visible because the span is adjacent to a covered culvert that connects with span 0700075. The stream channel is lined by masonry walls, and a small brick arch storm sewer is located through the southeast wingwall.

Historical and Technological Significance: The multi-girder with brick jack arch bridge is an altered example of what was a common bridge type in northern New Jersey from the late 1800s through about 1910. After 1910, with the development of the reinforced concrete deck, the brick jack arch deck became obsolete. Several examples of rolled beams with brick jack arches are extant in the county, but this span has built up beams. This example has been altered. Two of the bays have been filled with concrete, and the west elevation in hidden by a covered culvert placed ca. 1940.

A better example of the brick jack arch design is 0700063 built in 1898.

NJ and National Registers of Historic Places as of December 31, 1988, by NJDEP

Physical Description: The single span steel stringer and brick jack arch bridge is supported on ashlar abutments. The bridge is flared to support the Y-intersection of Valley Road and Central Avenue, and the span carries 2 sidewalks flanked by metal picket railings. The bridge spans 23' and the flared width measures an average of 95'. Tie rods are visible at the deck underside. The railing at one side of the bridge is set in concrete that is not from the original construction. Concrete retaining walls support the stream channel to one side of the bridge. No plans were located.

Historical and Technological Significance: The steel stringer and brick jack arch bridge constructed in 1899 is technologically significant because it is a well-preserved example of its type. The span is historically significant because it abuts an historic district. The span was constructed during the period of significance and contributes to the historic character of the historic district's setting. The stringer and brick jack arch span is an example of a common bridge type in the county from the late 1800s through about 1910. After 1910, with the development of the reinforced concrete deck, the brick jack arch deck became obsolete. The span is flared and measures wider than most spans of its type. The Essex County Freeholders Minutes indicate the masonry work was performed by Jacob Yost and the steel work was performed by Eugene B. Heddon, both local NJ contractors.

The span abuts the Erwin Park Historic District (Montclair Multiple Resource Area) listed on the State Register 9/29/86, and it is a potential National Register district. It is an area of well-preserved architecturally significant single-family houses dating from 1870ca Italianate through academic Colonial Revival with picturesque Colonial Revival predominating. In the late 1800s, the railroad was constructed making this area easily accessible from New York City, and the development of Montclair was spurred and promoted by the railroad as a residential community for New York City businessmen. Most of the houses in the area are well-maintained and retain their turn-of-the century character.

CONSULT DOCUMENTS SHPO Finding 6/6/91

SUMMARY The skewed stringer and brick jack arch bridge supported on ashlar abutments is flared with a steel thru girder at the long fascia. In 1990 two steel stringers were added adjacent to the deteriorated girder and many stringers were replaced. The span was built by Dover Boiler Works, a New Jersey firm active from 1901 through 1960. One of over 8 stringer and brick jack arch bridges in the county, the span has been altered, and it is not historically or technologically distinguished.

SETTING / CONTEXT The bridge carries a 2-lane collector road over a small stream in the extension to Branch Brook Park in Belleville adjacent to a commercial and residential area with structures dating from the 1910s to the 1970s. Branch Brook Park is one of the original parks developed as part of the nation's first county park system. The Essex County Park Commission began development of the park in 1896. The extension of the park dates to the mid 1920s.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. Branch Brook Park. 01/12/1981. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1867 coursed ashlar stone arch bridge with ringstones has corresponding parapets with replacement concrete caps. The stone has a vermiculated finish. The west parapet is damaged. The single-span bridge is a large and complete example of the early bridge type, and it is the oldest documented bridge in the county. Significant in its own right, it predates the National Register-listed park in which it is located, but it contributes to the historic character of the area.

INFOR MATION

Bibliography:
Essex County Engineers Office.
Essex County Board of Chosen Freeholders Minutes.
ONJH National Register File: Essex County, Branch Brook Park, Newark, New Jersey.

Physical Description: The single-span stone arch bridge is constructed of vermiculated coursed ashlar and finished with ringstones. Spanning 33' and measuring almost 30'-6" wide, the bridge carries a 2-lane road flanked by a concrete sidewalk and ashlar parapets with granite cap stones. A keystone on the east elevation is inscribed with the date, 1867, and the county freeholder minutes confirm the date of construction. The west parapet has missing stones at the north corner. No alterations to the span were noted. Plans were not located.

Historical and Technological Significance: The 1867 stone arch bridge is technologically significant because it is the earliest example of a stone arch bridge in the county, and it is well-preserved. Additionally, it is located in the extension division of Branch Brook Park. The park is listed in the National Register as a historic district, and the span is historically distinguished because it contributes to the historic character of the park. It is one of seven significant arch spans in Branch Brook Park (Criteria A and C).

Branch Brook Park is one of the original parks established as part of the development of the nation's first county park system. The Essex County Park Commission was formed in 1895, and they began plans for the development of two major parks, two reservations and four smaller parks. Branch Brook Park was the most important and extensively developed of the original parks. The park was divided into three divisions, the southern division was the first section of the park to be developed and construction began in 1896. John Bogart and N.F. Barrett, Landscape Architects and Engineers, provided the initial plans for the southern division of the park. They were terminated in 1897 due to cut backs in funds. In 1898, the Olmsted Brothers firm was hired, and they designed general plans for the completion of the southern division and new plans for the middle and northern divisions. The Olmsted Brothers firm was established by Frederick Law Olmsted, Sr. who is considered the founder of landscape architecture as a profession in this country. In 1857, he designed Central Park in New York, and he is responsible for many other noted landscape works in the country, such as the National Zoo in Washington, D.C., the United States Military Academy at West Point, the Capital Grounds in Washington, D.C., and the campuses of Harvard, Yale, and Stanford universities and Amherst College among others.

In the mid-1920s the land along the Second River between Newark and Belleville occupied by Hendricks Copper Mills including this span, was acquired by the Essex County Park Commission in order to extend Branch Brook Park. In 1927 Caroline Bamberger-Fuld donated over 2000 Japanese Cherry Blossom trees to the Essex County Park Commission to be planted in Branch Brook Park, and the trees were planted in the park extension along the Second River. The Essex County Park Commission has added to the collection through the years and it is now the largest display and variety of such trees in the United States attracting visitors from all over the country during the spring blooming season.

Boundary Description and Justification: The bridge is located within the Branch Brook Park Historic District. The area on all sides of the span is included in the nomination. For a detailed description of the exact boundaries of the district, refer to the nomination file at ONJH.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The handsome concrete deck arch bridge supported on concrete abutments has concrete parapets with decorative individual concrete cap stones and octagonal end posts. The bridge is technologically noteworthy because it is well-detailed. The span is one of 4 significant arch spans constructed in conjunction with the development of the nation's first county park system, and it contributes to the historic character of the park.

INFOR MATION

Bibliography:
Essex County Parks Department (Plans).
ONJH National Register Files: Essex County, Branch Brook Park, Newark, New Jersey. The Running Brooks and Other Sketches of Early Newark, by Edward S. Rankin, C.E., The Unionist-Gazette, Somerville, NJ, 1930.

Physical Description: The well-detailed elliptical reinforced concrete arch bridge carries a 2-lane road over a footpath and a small river in a county park. The bridge spans 66' and measures 58'-8" out-to-out. The arch measures 1'-6" at the crown and has an 8' rise. The sidewalks are flanked by concrete parapets with decorative cap stones. The spandrel walls, wingwalls and parapets are bush-hammered. Decorative concrete pilasters extend to concrete lampposts, but the original metal housings for the luminaries do not remain. The span is unaltered.

Historical and Technological Significance: The 1930 reinforced concrete arch bridge is technologically significant because it is a nicely detailed and well-preserved example of its type, and it was designed by a prominent civil engineer. The span is historically distinguished because it is a prominent feature in the National Register-listed Branch Brook Park. It is one of 4 arch bridges constructed between 1898 and 1930 as part of the development of the nation's first county park system, and it is one of seven total significant arch bridges in the park (Criteria A and C).

The bridge was designed by A. Burton Cohen (1883-1956), a consulting engineer based in New York City. He graduated from Purdue University with an engineering degree in 1910 and served as a bridge engineer for the Delaware Lackawanna & Western Railroad until 1920 when he established his own consulting firm. He was noted for his designs of concrete arch bridges, which include the 1926 open-spandrel ribbed concrete arch JFK Boulevard over PATH and Conrail span in Jersey City (0900008), and the Corning Concrete Arch Bridge in Corning, New York, which is the first bridge in the United States to be constructed with cast-in-place concrete piles.

Branch Brook Park is one of the original parks developed as part of the nation's first county park system, and it is listed on the National Register. The Essex County Park Commission was formed in 1895, and they began plans for the development of two major parks, two reservations and four smaller parks. Branch Brook Park was the most important and extensive of the original parks. The park was sectioned into three divisions, the southern, middle and northern divisions, and John Bogart and N.F. Barrett, Landscape Architects and Engineers, provided the initial plans for the southern division of the park. They were terminated in 1897 due to cut backs in funds. In 1898, the Olmsted Brothers firm was hired, and they designed general plans for the completion of the southern division and new plans for the middle and northern divisions. The Olmsted Brothers firm was established by Frederick Law Olmsted, Sr. who is considered the founder of landscape architecture as a profession in this country. In 1857, he designed Central Park in New York, and he is responsible for many other noted landscape works in the country, such as the National Zoo in Washington, D.C., the United States Military Academy at West Point, the Capital Grounds in Washington, D.C., and the campuses of Harvard, Yale, and Stanford universities and Amherst College, among others.

In the mid-1920s the land along the Second River between Newark and Belleville occupied by Hendricks Copper Mills was acquired by the Essex County Park Commission in order to extend Branch Brook Park. In 1927 Caroline Bamberger-Fuld donated over 2000 Japanese Cherry Blossom trees to the Essex County Park Commission to be planted in Branch Brook Park, and the trees were planted in the park extension along the Second River. In 1930 the park road paralleling the Second River known as Mill Street was realigned, and the bridge was constructed amidst the extensive cherry blossom tree collection. The Essex County Park Commission has added to the collection through the years and it is now the largest display and variety of such trees in the United States attracting visitors from all over the country during the spring blooming season.

Boundary Description and Justification: The bridge is located within a National Register-listed historic district. Therefore, the span and surroundings have been evaluated as significant. For a complete description of the boundaries, refer to the actual National Register nomination on file at ONJH.

SETTING / CONTEXT The bridge carries a 2-lane park road and sidewalks over a footpath in a county park. Branch Brook Park, listed on the National Register, is one of the nation's first county parks. The Essex County Park Commission, established in 1895, began construction of the southernmost division of the park where the bridge is located in 1896.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. Branch Brook Park Historic District. 01/12/1981. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1898 brick elliptical arch span ranks as one of the most architectonic bridges in the region. It is detailed with oversized rusticated voussoirs and keystone and matching pilasters. The spandrel walls and wingwalls are blond brick. In addition to its technological significance, historically the span is significant because it was built as part of the development of the nation's first county park system, and it is a contributing resource.

INFORMATION

Bibliography:
Essex County Engineers Office (Plans).
ONJH National Register File: Essex County, Branch Brook Park, Newark, New Jersey. Report of the Essex County Park Commission, 1901.

Physical Description: The richly detailed elliptical brick arch bridge spans 28', and carries a park road and sidewalks over a footpath in a county park. The bridge is flanked by plain concrete parapets with plain concrete pylons. The spandrel walls are constructed of buff brick, and the voussoirs are of stone masonry. Stone masonry pilasters are located at the corner of the brick-faced wing walls. The bridge has not been altered.

Historical and Technological Significance: The handsome brick arch bridge, constructed in 1898, is technologically significant because it ranks as one of the most architectonic bridges in the region, and it is an uncommon type. It is historically distinguished because it is one of 4 bridges constructed between 1898 and 1930 in National Register-listed Branch Brook Park Historic District, a Olmsted Brothers-designed park. The Newark park was developed as the centerpiece of the nation's first county park system. It is one of a total of seven significant arch bridges in Branch Brook Park, and all are evaluated as contributing resources (Criteria A and C).

The Essex County Park Commission was formed in 1895, and they began plans for the development of two major parks, two reservations and four smaller parks. Branch Brook Park was the most important and extensively developed of the original parks. The park was sectioned into 3 divisions. The southern division, where this span is located, was the first section of the park to be developed, and construction began in 1896. John Bogart and N.F. Barrett, Landscape Architects and Engineers, provided the initial plans for the southern division. They were terminated in 1897 due to cut backs in funds.

In 1898, the Olmsted Brothers firm was hired, and it appears that the firm revised the Bogart and Barrett plans for the completion of the southern division and developed the plans for the middle and northern divisions. The bridge plans do not specify a designer, so it is not known for certain if Olmsted detailed the bridge, but it is in the style of their work. The plans do not match exactly the bridge as built. The Olmsted Brothers firm was established by Frederick Law Olmsted, Sr. (1822-1903) who is considered the founder of landscape architecture as a profession in this country. In 1857, he designed Central Park in New York, and he and his firm are responsible for many other noted landscape works in the country, such as the National Zoo in Washington, D.C., the United States Military Academy at West Point, the Capital Grounds in Washington, D.C., and the campuses of Harvard, Yale, Amherst, and Stanford.

The southern division of Branch Brook Park was designed to be comparatively contrived and ornate with special expensive architectural stone ornaments and extensive specimen plantings. The brick arch bridge is the larger of two such detailed masonry spans located in the southern division of the park. The other is not included in the survey because it is less than 20' in length and is therefore classified as a culvert.

Boundary Description and Justification: The bridge is a contributing resource in a National Register-listed historic district. Therefore, the span and its surroundings are evaluated as significant. For a precise description of the district boundaries, refer to the National Register file at NJHPO.

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a slab bridge carrying NJ Transit tracks and US 22, which the slab bridge also crosses. The bridge is set in a county park, Weequahic Park. The park is one of the original county parks established in the late 1890s by the Essex County Park Commission, and was part of the nation's first county park system.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The open-spandrel ribbed concrete arch is composed of 4 ribs on a concrete substructure. The inner arches have spandrel columns while the outer ones are finished with continuous concrete spandrel walls. The deck is concrete. The Moderne-style parapets are finished with bush-hammered panels and chamfered caps. The concrete lampposts and luminaries remain in place. A good example of an uncommon bridge type, the span, part of an innovative 3-tier crossing, was designed by a noted engineer.

INFOR MATION

Bibliography:
Essex County Engineers Office (Plans).
Personal interview with A.G. Lichtenstein
A.G. Lichtenstein & Assoc. The New York Times. 2/12/1956. Obituary. Newark Public Library. Subject File: Weequahic Park.

Physical Description: The 1932 single-span ribbed open spandrel reinforced concrete arch bridge is composed of four ribs supporting a reinforced concrete slab deck. The interior ribs have spandrel columns while the outer ones are finished with continuous concrete spandrels. The arches are hinged at the abutments to allow the arches to rotate. The bridge spans 222' and measures 58' wide. The bridge is finished in the Moderne style. The parapets have bush-hammered panels with chamfered caps, and decorative concrete lampposts support luminaries. Constructed as part of a three-level crossing, the span was designed to carry a park road over 0718150, a slab bridge that originally carried 6 tracks of the Lehigh Valley Railroad over State Highway Route 29 (now US 22).

Historical and Technological Significance: The open spandrel ribbed arch bridge is technologically significant because it is a well-preserved example of an uncommon bridge type in the state. It is also part of an innovative three-level bridge crossing designed by a prominent civil engineer (Criterion C). It was constructed for the Essex County Park Commission and designed by A. Burton Cohen as part of a three-level crossing. 0718150, a 2-span slab bridge, was constructed under the same project, and it spans beneath this bridge. Mr. Cohen (1883-1956) was a consulting engineer in New York City. He graduated from Purdue University with a degree in engineering in 1910, and he served as Chief Engineer for the Delaware Lackawanna & Western Railroad until establishing his own firm in 1920. While with the railroad, Cohen worked almost exclusively in concrete, and he was awarded the American Concrete Institute's gold medal in 1927. Among his most distinguished projects are the Tuckhannock Viaduct on the DL&W's main line in Nicholson, PA and the grade crossing elimination projects for the railroad through Montclair, Orange and South Orange as well as Nassau County, New York. After leaving the railroad, he designed many other concrete arch bridges including the 1926 open-spandrel ribbed arch JFK Boulevard over PATH and Conrail in Jersey City (0900008) and the 1921 7-span Centerway Bridge over the Chemung River in Corning, New York, which is the first bridge in the United States to be constructed with cast-in-place concrete piles.

Weequahic Park was established as one of the original reservations in Essex County's ambitious county-wide park system established in 1895. Between 1896 and 1899 12 parcels in the what was then swampy land were acquired on the southern edge of Newark. The tract was upgraded to park status in 1910. A lake was created, and the west boundary of the park was extended. The extension included a race track for trotters that was retained. Other recreational facilities were added like the 1907 field house, the 1915 golf course, and the 1916 children's playground building, tennis courts, and comfort building. During World War II, Army barracks were built in the park, and after the war they were used as temporary quarters for military families to help ease the national housing crunch. The last of the barracks was removed in 1955.

Boundary Description and Justification: Although the bridge is located in a park setting, the span is evaluated as individually significant based on its technological distinction. It is part of a three-level structure, so the span under it (0718150) is also evaluated as significant. The boundaries include the two spans themselves and the retaining walls. The park does not appear to meet National Register criteria.

SETTING / CONTEXT The bridge carries a 2-lane park road over a small stream in a wooded area located in the South Mountain Reservation, a county park. The Essex County Park Commission was established in 1895, and it developed the nation's first county park system which was designed by Olmsted.. South Mountain Reservation was one of the original tracts secured by the commission.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Potential South Mountain Reservation Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The concrete deck arch bridge supported on a concrete substructure has ashlar veneer spandrel walls. The arch is detailed with ring stones, and the parapets are ashlar with granite cap stones. The square wire mesh reinforcement is visible at the spalled areas of the intrados. One of over 6 concrete deck arch bridges in the county, the short span is nicely detailed. While the bridge is not individually eligible for listing in the National Register of Historic Places, it would be a contributing element to a South Mountain Reservation Historic District under Criteria A and C should one be identified.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 20'-long stone arch bridge has coursed ashlar spandrel walls and rusticated ring stones. Ashlar parapets with granite cap stones flank the concrete sidewalks. Metal picket railings are set atop granite cap stones on flared ashlar wingwalls. The ca. 1875 bridge is one of 7 in Essex County. The bridge maintains exemplary integrity; no known alterations have been made. It is eligible for listing in the National Register of Historic Places under Criterion C as an example of stone arch technology.

INFOR MATION

Bibliography:
Essex County Engineers Office. Bridge Files.

Physical Description: The single-span stone arch bridge has a 20' span. The bridge is composed of coursed ashlar spandrel walls, voussoirs, and parapets and flared wingwalls with granite cap stones. The pointing is well maintained. Metal picket railings remain atop the wingwalls but have been removed from the parapets.

Historical and Technological Description: The undocumented ca. 1875 stone arch bridge is neither historically or technologically distinguished. It is a short-span example of a bridge type that is well represented in the county. No plans for the bridge were located at the county engineer's office and the bridge is undocumented to builder and date of construction. The bridge's setting is not distinguished and includes numerous 20th century intrusions. The are seven stone arch bridges built between 1867 and ca. 1875 in the county. Other examples include the 1869 Millburn Avenue bridge (0700027, Millburn Twp.), the 1868-69 Washington Avenue bridge (0700036, Belleville Twp.), and the 1867 Bridge Street bridge (0700068, Belleville Twp.).

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a small stream in a residential area dating to the 1910s. The bridge is about 50' from Bloomfield Ave. which is lined with early 1900s commercial buildings. A small concrete spillway is located about 5' downstream of the bridge. The bridge is located within a historic district in Glen Ridge Borough.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Glen Ridge Historic District. 08/09/1982. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The stringer and brick jack arch bridge supported on ashlar abutments has metal picket railings flanking each sidewalk. The stringers are rolled and metal tie rods are visible from the underside. The unaltered bridge is a well-preserved example of a common local bridge type from the 1880s through about 1910. Located within a historic district noted for its late-18th through mid-20th century architecture, the span was built within the period of significance and is a contributing element.

INFORMATION

Bibliography:
Essex County Engineers Office.
ONJH National Register File: Essex County, Glen Ridge Historic District.

Physical Description: The stringer and brick jack arch bridge supported on ashlar abutments spans 23', and carries a 2-lane road measuring 31' wide and 2 concrete sidewalks flanked by metal picket railings. Tie rods are visible at the underside of the bridge. Utility pipes were added under the bridge superstructure. No plans were located, but the span appears to be unaltered.

Historical and Technological Significance: The stringer and brick jack arch bridge is technologically significant because it is a well-preserved example of its type. It is historically significant because it is located within the Glen Ridge Historic District, and it is a contributing element having been constructed within the period of significance of the district. (Criteria A and C).

The ca. 1900 stringer and brick jack arch bridge is an example of a bridge type that was common in the county from about 1885 through about 1905. After 1905, with the development of the reinforced concrete deck, the brick jack arch deck became obsolete. Although a date of construction for the bridge could not be confirmed, the design and appearance of the span is consistent with other brick jack arch spans built in the county around the turn-of-the century.

The Glen Ridge Historic District is a suburban residential community of large well-preserved single-family homes dating from the late-19th through the mid-20th centuries and with tree-lined streets. The area was developed as a residential community by several entrepreneurs after construction of the railroad in the late 1800s made the area easily accessible, and therefore a practical location for affluent businessmen from Newark and New York City wishing to set up residence in a country setting. Most of the architectural styles popular in the late 19th and early 20th century are represented with the Queen Anne, Shingle, and Colonial Revival predominating. Examples of the Tudor Revival, Spanish Colonial Revival, and the earlier High Victorian styles are present. Glen Ridge Borough seceded from Bloomfield in 1895, and from the beginning, Glen Ridge residents acted to protect and preserve the character of their community. The Glen Ridge Park Association was formed in the late 1880s to acquire mill tracts and other commercial properties along the borough waterways. In 1910, the Borough Council became one of the first municipal bodies in the state to adopt a building code, and in 1921 Glen Ridge was one of the first municipalities in the state to enact a zoning ordinance.

Boundary Description and Justification: The bridge is evaluated as a contributing resource in a National Register historic district. Therefore both the bridge and its surroundings are evaluated as significant. For a complete description of the district boundaries, refer to the Glen Ridge Historic District National Register nomination on file at NJOHP.

CONSULT STATUS Individually Eligible. Listed. Branch Brook Park Historic District. 01/12/1981. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The handsome and well-proportioned steel arch and concrete bridge has scored octagonal corner piers that extend to concrete lampposts. Metal railings replace the original urn-shaped balusters in the balustrades, and guide rails were added at the curbs. The well-detailed Melan-type arch bridge is the longest of its type in the county, and it is one of 4 significant arch spans built within the period of significance of the historic district. It contributes to the historic character of the park.

INFORMATION

Bibliography:
Essex County Engineers Office (Plans).
Plain and Reinforced Concrete Arches, by J. Melan, authorized translation by D.B. Steinman, John Wiley & Sons, Inc., NY, 1917.
Macmillan Encyclopedia of Architects, Volume 1, Adolf K. Placzek, editor in chief, The Free Press, NY, 1982.
Architects in Practice New York City 1840-1900, by Dennis Steadman Francis for the Committee for the Preservation of Architectural Records.
ONJH National Register File: Essex County, Branch Brook Park, Newark, New Jersey. Report of the Essex County Park Commission, 1901.
Henry F. Withey and Elsie Rathburn Withey, Biographical Dictionary of American Architects, New Age Publishing Co., Los Angeles, 1956.

Physical Description: The elaborately detailed Melan-type steel arch bridge with plain concrete encasement spans 132' with a 16' rise. The crown thickness is 3', the radius of the intrados at the crown is 252', and the radius of the extrados is 304'. The bridge carries a 2-lane road and sidewalks flanked by modern metal railings that span between the original concrete pylons. The metal railings replace the original vase-shaped concrete balustrades lost at an unknown date. The plans indicate that the Melan reinforcement consists of a series of equally spaced curved steel members composed of 2 pairs of angles measuring 3" x 3" x ½" separated by lattice bars measuring 2" x ¼". Engaged octagonal columns at the bridge corners continue as the fully articulated octagonal lampposts. The engaged columns are scored to give the appearance of ashlar. The only known alteration to the span is replacement of the railings.

Historical and Technological Significance: The 1905 steel arch bridge is technologically distinguished as an exceptionally well-detailed example of a span with the Melan-type reinforcing system, a patented design. It was designed and constructed by a prominent firm, the Concrete-Steel Engineering Company. The span is historically distinguished because it is one of 4 bridges built between 1898 and 1930 in the National Register-listed Branch Brook Park Historic District. The park was developed as part of the nation's first county park system, and it was done after plans prepared by the Olmsted firm. It is one of a total of seven significant arch spans in Branch Brook Park (Criteria C).

Joseph Melan, a Viennese engineer, developed the reinforcing system which consists of a series of parallel iron or steel I-beams curved to the profile of the soffit. He was granted an American patent for the invention in 1894, where it quickly became popular because the design combined two constructions familiar to American builders, the iron arch rib and the masonry arch. Fritz von Emperger, a German-born engineer, built the first Melan arch span in this country in Rock Rapids, Iowa, and he is credited with popularizing the technique in the United States. Emperger made additions to the Melan system, adding a beam in the deck and joining the deck and arch beams by means of bars set on radial lines. He was granted a patent for these changes in 1897.

Plans for the span indicate that it was designed for the Essex County Park Commission as a major landscape element of the Branch Brook Park by the Concrete-Steel Engineering Company, consultant. The Concrete-Steel Engineering Company was formed in 1901 by Edwin Thacher and William Mueser, and it was headquartered in the Park Row Building in New York City. The firm was responsible for the design of many important Melan-type arch bridges in this country including the 8 span Grand Avenue Viaduct, Milwaukee, Wis., built in 1907; a 7 span Melan arch in Wichita, Kansas, built in 1911; the 6 span Hudson River Bridge at Glen Falls, NY, built in 1914-15; the bridge over the Mississippi River at Minneapolis composed of 5-231' spans built in 1915-16; and the single span bridge at Scranton, PA. built in 1907.

Edwin Thacher was a prominent civil engineer having obtained patents for the "Thacher Cylindrical Slide-Rule"; "Thacher Steel Bridge Truss"; "System of Concrete Steel Arches" and "Thacher Combination Bridge Truss" among others. He held the positions of Chief Engineer for the Decatur Bridge and Construction Company of Decatur, Alabama, and the Keystone Bridge Company of Pittsburgh, Pennsylvania before opening his own Consulting Engineering Office in Louisville, Kentucky where he was responsible for the design of many truss spans including the 1891 Walnut Street Bridge crossing the Tennessee River in Chattanooga, and the 1892 Costilla Crossing Bridge across the Rio Grande in Colorado, an example of the Thacher truss patented in 1884 and designed to reduce the effect of temperature stresses on the truss members. Thacher formed a partnership in 1894 with Mr. W. H. Keepers and Mr. Wynkoop in Detroit, Michigan. Mr. Wynkoop dropped out of the partnership in 1895 and the partnership of Keepers and Thacher continued until it was

dissolved on October 5, 1899. The firm constructed the concrete steel arch bridge over the Kansas River at Topeka, Kansas, at that time the largest bridge of its kind in the United States, as well as many other bridge structures. The 1897 West Broadway Avenue Melan-arch bridge (1600017, Passaic County) and the 1899 Wyckoff Avenue Melan-arch bridge (020033E, Bergen County) are attributable to Thacher. Thacher remained with the Concrete-Steel Engineering Company until his retirement in 1912. The 1896 Grand Avenue bridge in Monmouth County (130MT50) is attributed to William Mueser.

The architectural detailing was done by Babb, Cook, and Willard Architects, a partnership between George Fletcher Babb, Walter Cook, and Daniel Willard. The firm was responsible for the design of many private homes and buildings in New York and New Jersey, and they also designed several buildings in other areas of the country. Their most important works include the 1899-1901 Andrew Carnegie House (now the Cooper Hewitt Museum), the 1885-86 De Vinne Press Building, New York, and the 1897-98 F.B. Pratt House, Brooklyn, NY. George Fletcher Babb was born in New York in 1836, and he moved to New Jersey early in his childhood. He designed several New Jersey homes while working in the office of T. R. Jackson in New York City. By 1868 he was the senior draftsman in the office of Russell Sturgis. In 1877, Babb went into partnership with Walter Cook, born in 1846 and an 1869 graduate of Harvard. Cook studied in Munich from 1871-1873 and in Paris under Joseph Auguste Emile Vaudremer from 1873-1876 before joining Babb in partnership. In 1884, Daniel W. Willard joined the partnership. By 1890 Cook was the principal designing partner.

The bridge spans a lake and park road through Branch Brook Park in Newark, and was termed the Midlake Bridge. Branch Brook Park is one of the original parks established by the Essex County Park Commission as part of the development of the nation's first county park system. The park is listed on the National Register as a historic district. The Essex County Park Commission was formed in 1895, and they began plans for the development of two major parks, two reservations and four smaller parks. Branch Brook Park was the most important and extensively developed of the original parks. The park was divided into three divisions, the southern division was the first section of the park to be developed and construction began in 1896. It was designed to be comparatively ornate with special expensive architectural stone constructions and specimen plantings. The northern division was designed to have a natural rustic style, and the middle division was designed to have an intermediate style transitioning between the ornate southern division and the natural style of the northern division. The bridge is located between the southern and middle divisions, and it was designed with elaborate detailing to be compatible with the style of the southern division. Park Avenue was known as Fifth Avenue in Newark at the time of construction. The bridge was built to connect either side of Fifth Avenue through the park. The road was transferred from the jurisdiction of the County Freeholders to the Essex County Park Commission in 1903, and construction of the bridge was completed in 1905.

Boundary Description and Justification: The bridge is located within the Branch Brook Park Historic District, and so it and its surroundings are evaluated as significant. For the exact boundaries of the district, refer to the National Register file maintained by ONJH.

DESIGNER/PATENT J. OWEN, R.WATSON, CO.ENGS. **BUILDER** NEW JERSEY BRIDGE COMPANY

SETTING / CONTEXT The bridge carries a 2-lane collector road and sidewalks over a major river in a commercial area with structures dating from the 1950s to the present. The bridge is known as the Avondale Bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The rim bearing swing span bridge supported on an ashlar substructure is composed of a hybrid pinned/riveted Warren thru truss main span with built-up floorbeams and Warren pony truss approach spans. The electrical system was replaced in 1984. The swing span reflects the state of design knowledge of the time which makes the span an important example of the evolution of movable bridge technology. It is one of four thru truss swing spans in Essex County. All are significant.

INFOR MATION

Bibliography:
Essex County Engineers Office. (Plans)
Essex County Board of Chosen Freeholders Minutes.
Manasquan, New Jersey, compiled by Townsfolk for the Diamond Jubilee under the sponsorship of the Manasquan Chamber of Commerce, 1962.

Physical Description: The rim bearing swing-span bridge is composed of a hybrid pin-connected and riveted double-intersection Warren through truss swing-span and two Warren with verticals pony truss approach spans. The bridge measures 364' in length and carries a 27' roadway and 2 cantilevered sidewalks. The fish-belly shaped top chords are of built-up back-to-back channels connected by lacing at the bottom and a cover plate for most of the span except at the center tower where it is composed of pin-connected stamped eye bars. The same arrangement is also used on the 1906 Gregory Ave. bridge in Passaic County (1600002). The arrangement permits the Warren trusses to act as simply supported span when the bridge is taking live loads. An unusual detail is the transition panel between the pin-connected and rivet-connected portions of the top chords where it is composed of eye bars built up with rivet-connected angles connected by lacing. The diagonals and the lower chords are built up with two pairs of back-to-back angles connected by lacing. They have been strengthened with additional material bolted to the webs. The vertical members are built-up with two pairs of back-to-back angles separated by lacing. The sidewalks are flanked by modern 3-rail metal railings.

The power source and controls for the bridge were altered in 1984 when new motors, generators, and controls were installed. The equipment house was moved to its present mid-span location at that time. The gearing remains the same or inkind replacements. Other work done in 1984 includes repairs to the steel superstructure, rest piers, abutments, and fenders and replacement of the stringers and deck. The truss diagonal members were repaired. The gate houses and operators house, and overhead generating room, including supporting members, also date to the 1984 rehabilitation.

Technological and Historical Significance: The 1904-05 swing-span bridge, designed by the Bergen and Essex county engineers, is historically significant because it is one of fewer than ten spans in the state constructed by the New Jersey Bridge Company, a New Jersey bridge manufacturer who successfully marketed bridges nationally. This is one of if not the largest bridge in New Jersey that they erected. The bridge is technologically significant because its construction details reflect the state of design knowledge at that time which could only account for simply supported spans for live load considerations. The pin-connected top chords are for the tension-only, double cantilever configuration the span assumes during operation (when it is not supported at the toe end by the bearings on the rest piers). The rivet-connected Warren trusses are for live-load configurations. The presence of the not-rigid eye bars would not permit transfer of live-load stresses between spans. (Criteria C). Although the bridge and operating machinery have been altered, the historical and technical significance of the span remain, and the bridge maintains integrity of function.

The New Jersey Bridge Company of Manasquan, New Jersey, was established in 1890 by two men from Canton, Ohio, Mr. Wyckoop and Mr. Braly. The company built many steel bridges in New Jersey, and it employed 15 to 20 draftsmen and up to 100 construction workers. Their bridges have been identified from Maine to Michigan. Financial difficulties incurred due to problems on a bridge in Portland, Maine, caused the failure of the firm in 1907. The F. W. Stillman Company acted as the general contractors for the bridge construction.

Boundary Description and Justification: The bridge has been evaluated as individually significant. The boundary is thus limited to the span itself and includes the superstructure as well as the substructure.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The triple-intersection Warren thru truss swing-span bridge with 1975 replacement approach spans is supported on concrete abutments and an ashlar center pier. It was significantly altered in 1975 when the operating mechanisms (gears, motors, controls., overhead generator house) were replaced with modern equipment. The span is historically important, and the unusual trusses are fairly complete. The bridge still operates in the original manner and is thus noteworthy.

INFOR MATION

Bibliography:
Essex County Engineers Office: Bridge Plans.
Essex County Board of Chosen Freeholders Minutes.

Physical Description: The 3-span bridge is composed of a riveted triple-intersection Warren through truss rim-bearing swing-span, and two approach spans. The bridge measures 326' in length and carries a 38' roadway and 2 cantilevered sidewalks. The trusses have an unusual profile because of the parabolic-shape of the top chords and the curved connection between the top chords and the end posts. The latter is an aesthetic consideration, not a structural one. The top chords are built-up members composed back-to-back channels connected by lattice at the bottom and a cover plate at the top. The diagonal and vertical members are built-up with two pairs of back-to-back angles separated by lacing or batten plates. The lower chords are back-to-back channels connected by lattice. The trusses themselves have some strengthening, but they are for the most part well preserved. The cantilevered sidewalks are enclosed by the original wrought-iron lattice-pattern railings.

In 1975, the bridge was rehabilitated. The east approach span was replaced with prestressed voided slab beams, stringers were replaced and the girders and floor beams were repaired at the west approach span. The floor beam stiffener angles and stringers were replaced at the swing-span, the bridge deck was replaced, new concrete pedestals were placed at the west quarter pier, a new concrete header was added at the east quarter pier, and the timber fender system was repaired. The truss diagonal members were strengthened by adding plates and angles to form a box section. The gate house at the east approach and the overhead generator room located at the center of the span date to the 1975 rehabilitation. In 1992 the timber fenders were repaired and several sidewalk brackets were replaced.

The operating mechanisms were also replaced in the 1975 rehabilitation, but the span still operates in the original manner, by means of a rack and pinion drive mechanism, now powered by new electric motors (the bridge was originally powered by a steam engine) activated by modern control panels . The pinions and gears (one open set, one enclosed reducer) are now at the side of the drum girder, which rides on inkind replacement wheels, rather than in the original position at the center. There are also new screw jack end lifts rather than wedges. The drum girder, drum girders, radial, and floor beams are original, although they too have been strengthened.

Technological and Historical Significance: The 1908 Clay Street rim-bearing swing-span bridge, located in the industrial heart of Newark, was designed by J. Owen, the Essex County engineer and constructed by A. E. Sandford Co., a local contractor. The span replaced an 1889 wrought iron draw span built to help alleviate heavy traffic on the Bridge Street Bridge (0700H03) located downstream. The swing span was one of at least two in Newark that were powered for many years by a steam engine (Jackson Street (0700H02) is the other. Its steam engine is now in the collection of the Newark Museum).

The bridge is a large example of its type, and the truss type of the main span, a triple-intersection Warren thru truss, is not common. While the bridge has been so altered, the trusses and how the span operates remains fairly original. Because of its size, operable condition, truss type, and historic associations with the development of Newark, one of the premier industrial centers in the region, the span is historically and technologically distinguished (Criteria A,C). It is one of three similar rim-bearing swing span bridges in the center of Newark, and the other two (0700H02, 0700H03) have also been evaluated as significant.

Boundary Description & Justification: The movable span of the bridge is evaluated as significant. The approach spans have been either replaced or severely altered so that they no longer have historical or technological significance. The boundary is thus limited to the movable span and the center pier upon which it bears when in the open position.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS DOE 05/28/80. SHPO Letter 6/30/95.

SUMMARY The lattice thru truss swing span bridge is supported on a stone substructure. It has been significantly altered. In 1991 repairs to the span included strengthening the truss lower chord and diagonals, and replacing the drum girder, wheel assembly, and floor beams. Additionally, the entire operating mechanism was replaced. The only original feature of the span is the truss lines, but because they are rare examples of an uncommon type, the span remains technologically and historically noteworthy.

SUMMARY The rim-bearing Pratt thru truss swing span bridge is supported on an ashlar substructure with concrete caps. In 1981 the east gate house was removed, a new overhead control house was erected, and the operation was rendered fully automated. The trusses were also repaired. One of three operational rim-bearing swing spans in the industrial heart of Newark, the span is evaluated as significant based on its type and historical associations despite alterations.

INFORMATION

Bibliography:
Essex County Engineers Office. (Plans)
Essex County Board of Chosen Freeholders Minutes.

Physical Description: The rim bearing swing-span bridge is composed of a riveted Pratt with counters thru truss with curved top chords swing span, and two built-up deck girder approach spans. The bridge measures 371' in length and carries a 39' roadway and 2 cantilevered sidewalks. The top chords are built-up back-to-back channels connected by lattice at the bottom and a cover plate at the top. The diagonal members and the bottom chord are back-to-back channels connected by lacing. The vertical members are built-up with two pairs of back-to-back angles separated by lacing. The sidewalks are flanked by modern 3-rail metal railings. Some of the members, particularly the outside panel members, have been strengthened by additional plates connected with high-strength bolts.

The bridge was rehabilitated in 1981, and although much of the operating machinery and gearing were replaced, some of the new fabric is inkind replacement, and the span still operates in the original manner. The electrical system was completely updated in 1981 as were the operating controls and operator's house, located adjacent to one quadrant of the span. The movable span rotates on wheels affixed to the bottom of the drum girder and inside the rack. While the rack, pinion, and bevel drive gear sets appear to be 1981 replacements, they are inkind and in the original locations. The operation of the bridge was automated in 1981 so that the entire process was performed by engaging a single switch. The automated process was disengaged because the process could not be halted when problems arose. The built-up radials located inside the drum and connected to the center pin and pedestal have web plates. The bearings are now the screw jack type, and they too were installed in 1981. Other 1981 work includes welded floor beams added to the deck girder approach spans and concrete caps added to the ashlar abutments and wingwalls. The bridge deck and stringers were replaced, and the timber fender system was repaired.

Technological and Historical Significance: The 1912 swing-span bridge, located in the industrial heart of Newark, was designed by the county engineer and constructed by the American Bridge Company. The bridge is technologically significant because it is an operating example of an increasingly rare bridge type. It is one of only four known rim bearing swing-span bridges in the county, and it is one of three with curved top chords and curved tops to the end posts. The truss design was popular locally and may well have been done by James Owens, the Essex County Engineer and his staff (Criterion C). In addition to its technological significance, the bridge is associated with the industrial development of Newark, one of the leading industrial centers of the region prior to World War II. The bridge was rehabilitated in 1981, and although some of the work to it resulted in the loss of historic fabric, particularly in the area of the controls and power source, the bridge retains enough of its original material and design to rank as one of the noteworthy swing spans in the state. The bridge is a rim-bearing rather than a center bearing because of its size.

Boundary Description and Justification: The boundary is limited to the swing span and the substructure related to it (pivot pier and rest piers). The approach spans have been so altered that they have lost integrity of original design. Since it is the technology of the swing span that is being recognized, it is appropriate to limit the boundary to just that span.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The T beam bridge is supported on concrete abutments that are continuous with stone retaining walls along the concrete stream channel. Concrete balustrades of standard design border the concrete sidewalks. In 1969 the retaining walls were heightened at one side of the span, and the concrete invert slab was added to the stream bed. The short span is a common type, and it is neither technologically innovative nor historically distinguished.

DESIGNER/PATENT NJ STATE HWY DEPT **BUILDER** ANDREW O'NEILL CO., MEADE CO.

SETTING / CONTEXT The nearly mile long viaduct is in an industrialized area and crosses former Lehigh Valley RR r-o-w. The viaduct is at the western terminus of the elevated portion of the "superhighway" approach road to the Holland Tunnel, and it originally carried 2-directional traffic. Route 1 Extension was the prototype in the development of the elevated limited access highway that eliminates grade crossings.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS MOA 7/22/92. SHPO Letter 6/30/95.

SUMMARY The 39-span viaduct composed of T-beam, stringer, and thru girder spans is historically significant as part of the "superhighway" built by the state to solve the traffic problems associated with the Holland Tunnel. It is part of the elevated portion of the road to the tunnel. The viaduct embodies the distinctive characteristics of type and method of construction used by the state's designers on the historic and innovative route. Northbound traffic is carried on the 1949 parallel structure.

CONSTRUCTION DT 1929 **ALTERATION DT** **SOURCE** PLANS

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER** ANDREW O'NEILL CO.

SETTING / CONTEXT The viaduct carries 2-directional traffic of a local street over a railroad r-o-w and a local street. It is a transition from the elevated portion of the "superhighway" approach road to the Holland Tunnel, and it is contiguous to the Pulaski Skyway portion or western end of that historic and innovative roadway. The surrounding area is industrial.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS MOA 7/22/92. SHPO Letter 6/30/95.

SUMMARY The 39-span viaduct is composed of T beam, encased stringer, and deck girder spans, and it retains its original pipe railings. It serves as an access ramp to the elevated portion of the historic approach road to the Holland Tunnel, which is considered America's first superhighway. The bridge is significant for its association with that roadway. Technologically it is representative of period bridge design used by the State Highway Department.

CONSTRUCTION DT 1926 **ALTERATION DT** 1947 **SOURCE** PLANS

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER** STANGE CONSTRUCTION CO.

SETTING / CONTEXT The bridge carries one direction of a divided highway over a local street in an industrial section of Newark north of Newark Airport. The highway has been widened thus affecting the original setting and integrity of this section of the road, developed in 1925-1932 as the Route 1 Extension or approach road to the Holland Tunnel. This section was comprised of an elevated highway on fill with overpasses over local roads and highways.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 9/11/91, Letter 6/30/95.

SUMMARY The structure has been so compromised by the subsequent changes that it no longer contributes to the historic character of the resource. Addition of the northbound span to the east and the widening to the west act to virtually encase the original structure and obliterate its historic setting. Modifications also included the removal of the original balustrade and block paving. The concrete encased stringer type construction utilized on this span is typical of the route and state design.

SETTING / CONTEXT The bridge carries US 1&9 Truck, a 4-lane divided highway and sidewalks, over a major river and a 2-lane collector road in an industrial area dating from the turn-of-the-century to the present. The bridge spans the Passaic River between Hudson and Essex Counties just south of the Pulaski Skyway. It is located on the highway that serviced the area before the Skyway was completed. Trucks were excluded from the Skyway for safety reasons.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The steel vertical lift bridge supported on a concrete substructure has a Warren truss with verticals main lift span and haunched steel girder with floorbeams approach spans. The original metal railings remain on the span. One of the few highway vertical lift spans in the region, the bridge is technologically noteworthy because it is a long and well-preserved example of an important type. It is historically significant because of its association with an important early state highway.

Bibliography:
New Jersey Department of Transportation (Plans).
Bridge Engineering, by J. Waddell, John Wiley & Sons, Inc., NY, 1916.
"Morris Goodkind, Bridge Engineer Dies," from The Daily Home News, New Brunswick, NJ, Sept. 7, 1968, pp. 1,12.
Brown, Kathi Ann. Design By Diversity. Kansas City, Missouri: The Lowell Press, 1989.

Physical Description: The 18-span vertical lift bridge is composed of a steel Warren through truss with verticals and a polygonal top chord movable main span, and 17 girder with floor beams approach spans. The bridge measures 2005' long, and it carries a 52' wide barrier divided roadway. The lift span measures 332.5' long. The span provides 40' clearance over the waterway in the closed position, and 135' when fully lifted. The approach spans were rehabilitated 1990ca, and chain-link-fence was attached along portions of the approach. The original metal railing remains for most of its length, and the lift span appears unaltered.

The operation of the lift is controlled from the operator's house which is located about 10' above the sidewalk within the tower at the northwest corner of the lift span. A second control house, which is no longer used, is located in the southwest tower. The gate house and a storage house are located opposite the operator's houses on the east side of the span. The houses in the towers, the control panel, and machinery are all original. The motors that initiate the lift are in the machine houses that are located at the top of both towers. A total of twelve motors, four drive motors and two break motors at each corner of the towers, provide power to operate the bridge. The span is lifted at four points by means of chains that attach to either end of the lift girders. The chains are retracted by the gears, thus moving the span upward, and simultaneously allowing the counterweights, which are located beneath the machine houses, to move downward. The motors were designed to automatically adjust the power supplied in order to ensure the span remains level as it is lifted.

Historical and Technological Significance: The 1939 viaduct is technologically significant because it is a well preserved and large example of an important bridge type. It ranks as one of the longest spans of its type in the region. It is one of two highway vertical lift bridges in the county. The other one is NJ 280 over the Passaic River (0731161) between Newark and Harrison, and it was designed by Waddell and Hardesty in 1945. The bridge is historically noteworthy because it was designed by a prominent consulting engineer firm of Ash-Howard-Needles & Tammen that did much to both pioneer and promulgate the bridge type (Criterion C).

The bridge was built on a new alignment alongside the bridge that carried the Lincoln Highway. That span was removed after construction of this bridge was completed. The original approach roadway to the previous non-extant bridge remain and serve as secondary roads that terminate at either side of the Passaic River. The Lincoln Highway was developed as a result of nationwide support for an "improved" or rock cross country highway. The Lincoln Highway Association was formed in 1913 to lobby and support such a road, but the effort resulted in little in the way of new construction. In New Jersey the highway followed existing roads that were for the most part already improved (paved) through routes. The Lincoln Highway was the main road through the area before the completion of the Pulaski Skyway (1932), which is just south of the 1939 vertical lift bridge.

The firm of Ash-Howard-Needles and Tammen, consulting engineers on the vertical lift bridge project, was one of the nation's leading designers of movable spans. The firm's principal members began their careers in the 1890s and 1900s under the tutelage of bridge engineer J. A. L. Waddell and his partner John Lyle Harrington, who together receive much of the credit for developing the modern vertical lift bridge technology in the United States. In 1914 Waddell and Harrington dissolved their partnership, and a new firm, Harrington, Howard, and Ash, was formed; in 1928 the partnership became Ash-Howard-Needles and Tammen. From 1914 to 1928 the firm designed more than 45 vertical lift bridges, 13 bascule bridges, and six rolling bascule bridges, including a series of 18 movable bridges across the Welland Canal in Ontario, Canada. During the New Deal era of the 1930s, the firm became one of the leading recipients of Public Works Administration bridge projects, and was one of the most active designers of movable spans in New Jersey. In 1930 the firm completed work on the Burlington-Bristol vertical lift bridge across the Delaware River from New Jersey to Pennsylvania. Their work also included the bascule bridges for the Ocean Highway in Cape May County (3900003-3900006), over six bascule bridges for the New Jersey State Highway Department, and three smaller vertical lift spans in southern New Jersey (1710152, 0806151, 0817151).

November 12, 2002

The bridge approaches were designed by the New Jersey State Highway Department Bridge Division under the direction of Morris Goodkind, a prominent bridge engineer. Morris Goodkind was Chief Bridge Engineer of the State Highway Department from 1925 to 1955. Many of the state highway bridges in use today were constructed during his tenure. He won many awards for his designs including an award from the American Institute of Steel Construction for the Oceanic Bridge over the Navesink River (1300S31), built in 1939-1940, as the most beautiful movable bridge built during that year in the country, and similar award for the Passaic River Bridge between Newark and Kearny, built in 1941, and the Absecon Boulevard Bridge in Atlantic City, built in 1946.

Boundary Description and Justification: The bridge is evaluated as individually significant for its technological distinction. The boundary is limited to the bridge itself including the moveable main span, the approach spans, and the substructure.

SETTING / CONTEXT The bridge carries a narrow 2-lane collector road over a major river bordered by wooded undeveloped land. Light industrial buildings constructed in the 1960s through the 1980s are located to the south of the bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span riveted thru girder with encased floorbeams bridge is supported on a concrete substructure. In 1969 the bridge was redecked. Gunite was added at the abutments and floorbeams. Concrete obelisk lampposts without luminaries remain on top of the girders at the bridge corners. One of over 8 pre-WW II thru girder bridges in the county, the span is an altered example of a common type and is not distinguished.

SETTING / CONTEXT The viaduct carries a 4-lane divided highway and sidewalks over a 6-lane divided highway, and Amtrak and Conrail tracks. The area is industrial dating from the turn-of-the-century to the present. The viaduct crosses the historic rights-of-way of the Pennsylvania and Lehigh Valley railroads in an industrial section of Newark.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The viaduct is composed of 2 encased Warren deck truss main spans and 28 approach spans composed of either encased thru girders with floorbeams or deck girders with floorbeams. The high parapets are panelled and have modern luminaries attached. The viaduct is well-preserved, the deck truss was a common span type by 1938. More significant examples, such as the 1910 viaduct (0900016), the approaches to the Pulaski Skyway (0901150), and the helix (3800031), better represent the type.

SETTING / CONTEXT The bridge carries 2 tracks of the Lehigh Valley Main Line railroad over US 22, a 4-lane divided highway, and is set at the border of Weequahic Park. The bridge is the center level of a 3 tier grade separation with 0700079 spanning overhead. Weequahic Park is one of the original county parks established in the late 1890s as part of the nations first county park system.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span reinforced concrete slab bridge supported on a concrete substructure is constructed on a large skew. The surface of the fasciae is sawtoothed rather than flush, and the panelled parapets follow the shape. The well-detailed span is part of an innovative engineering solution for the common intersection of two roads and a railroad and is technologically noteworthy. It is also the work of noted engineer A. Burton Cohen, a national leader in the design of concrete bridges.

INFOR MATION

Bibliography:
Essex County Engineers Office (Plans).
Personal interview with A.G. Lichtenstein
A.G. Lichtenstein & Assoc. The New York Times. Obituary, 2/12/1956.
Newark Public Library. Subject File: Weequahic Park.

Physical Description: The 1932 2-span reinforced concrete slab bridge with plain spandrels is constructed on a large skew. The bridge spans 132' and measures 248' wide. Because of the degree of skew, the bridge has a sawtooth profile, a common 1930s design solution to the problem (also used at 0917169 on the Holland Tunnel approach in Weehawken). Constructed as part of a three-level crossing, the span was designed to carry 6 tracks of the Lehigh Valley Railroad over State Highway Route 29 (now US 22). All but 2 tracks have been removed from the span. An open spandrel ribbed arch bridge (0700079), built at the same time, spans over the bridge, and it carries a park road. Both bridges are visually unified by the same concrete parapets that are finished in the Moderne style with flat panels and chamfered caps. The bridge is well preserved.

Historical and Technological Significance: The slab bridge is technologically significant because it is part of a well-preserved example of an innovative three-level bridge crossing designed by a prominent civil engineer (Criterion C). The slab bridge was constructed for the Essex County Park Commission and designed by A. Burton Cohen (1883-1956), a prominent engineer noted for his work in concrete. Before founding his own consulting engineering firm in New York City in 1920, Cohen had a distinguished career as the bridge engineer for the Delaware Lackawanna & Western Railroad's ambitious programs of eliminating grade crossings in New Jersey and improving its main line in Pennsylvania. Perhaps his most monumental work is the Tunkhannock Creek Viaduct in Nicholson, PA. His grade crossing elimination projects in New Jersey include Montclair, South Orange, and Orange. He graduated from Purdue University with an engineering degree in 1910, and he joined the railroad shortly thereafter. He was awarded the American Concrete Institute's gold medal in 1927. While in private practice, he designed many concrete arch bridges including JFK Boulevard over PATH and Conrail in Jersey City, and the 1921 7-span Centerway Bridge over the Chemung River in Corning, New York, which is the first bridge in the United States to be constructed with cast-in-place concrete piles.

Weequahic Park was established as one of the original reservations in Essex County's ambitious county-wide park system established in 1895. Between 1896 and 1899 12 parcels in the what was then swampy land were acquired on the southern edge of Newark. The tract was upgraded to park status in 1910. A lake was created, and the west boundary of the park was extended. The extension included a race track for trotters that was retained. Other recreational facilities were added, such as the 1907 field house, the 1915 golf course, and the 1916 children's playground building, tennis courts, and comfort building. During World War II, Army barracks were built in the park, and after the war they were used as temporary quarters for military families to help ease the national housing crunch. The last of the barracks were removed in 1955.

Boundary Description and Justification: Although the bridge is located in a park setting, the span is evaluated as individually significant based on its technological distinction. It is part of a three level structure, so the span above it (0700079) is also evaluated as significant. The boundaries include the two spans and the retaining walls. The park does not appear to meet National Register criteria.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The earth-filled, reinforced-concrete arch with plain concrete parapets is a representative example of over 15 other existing arches built by Gloucester County between 1912 and 1940. William C. Cattell, the county engineer from 1909 to 1942, preferred the parapet arches for the creek crossings in the hillier western sections of the county. An eligible example of the bridge type is located in the Mullica Hill Historic District (#0825150).

TYPE THRU GIRDER **DESIGN** ENCASED **MATERIAL** Steel

 # SPANS 1 **LENGTH** 93 ft **WIDTH** 20 ft

CONSTRUCTION DT 1914 **ALTERATION DT** 1935 **SOURCE** COUNTY ENGINEER

DESIGNER/PATENT WILLIAM C. CATTELL, CO. ENG. **BUILDER** SUBURBAN CONSTRUCTION CO.

SETTING / CONTEXT The two-lane wide, encased thru girder spans a single-track railroad running through an older, well-preserved, 19th-century residential neighborhood in Woodbury City. The bridge is within a large historic district that incorporates Woodbury's commercial and residential areas. A nomination has been submitted for review by ONJH. The bridge appears to be a contributing element.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Agreed Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span, encased, thru-girder with floor beams bridge has stone abutments. The bridge was designed by William C. Cattell, the county engineer, and built by the Suburban Construction Co. of Philadelphia. It was repaired and strengthened by the McClintic-Marshall Co., a division of Bethlehem Steel, in 1935. The bridge is eligible because it falls within the period of significance of the historic neighborhood in which it is located.

INFOR MATION

SOURCES:
Gloucester County Engineer. Bridge File Cards and Plans, #0802i14, 1914-1935.
Office of New Jersey Heritage. Woodbury Historic District Nomination. 1991.
Waddell, J. A. L. Bridge Engineering. 1916.

PHYSICAL DESCRIPTION: The single-span bridge is an above grade crossing of the former Pennsylvania-Reading Seashore Lines, now Conrail. The bridge is a 93'-span encased thru girder with encased floor beams. It is supported on coursed-stone abutments. The bridge has a 20'-roadway and two narrow concrete sidewalks on the interior side of the girders.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Hunter Street Bridge lies within the proposed Woodbury Historic District, a large historic district that incorporates Woodbury's commercial and residential areas. Built in 1914, the bridge was constructed within the dates of significance of the proposed district (c.1715-1941) and contributes to the historic character of the well-preserved, 19th-century residential neighborhood in which it is located. The bridge serves to connect the residential area with the downtown commercial area to the west.

The bridge was constructed by the Suburban Construction Company of Philadelphia after plans approved by the Gloucester County Engineer, William C. Cattell. In 1935 the bridge was repaired by the McClintic-Marshall Co., a division of Bethlehem Steel, but the overall design of the bridge was not significantly altered. The bridge is a representative example of a thru-girder bridge technology, and is historically significant because of its location within a proposed historic district. A nomination for the historic district has been submitted for review by ONJH.

Condit, Carl W. American Building Art: The Twentieth Century. New York: Oxford University Press, 1961.
New Jersey Department of Transportation. Bridge File 0805154. 1930.

PHYSICAL DESCRIPTION: The skewed, two-lane, six-span, 182'-long, 40.5'-wide bridge survives with very few alterations. The bridge is a continuous reinforced-concrete slab with reinforced-concrete bents, floor beams, and abutments. The bents are composed of concrete columns and longitudinal beams spaced 17' apart except for the central bents which is separated from its neighbors by 22'6". The floor beams do not extend across the middle two spans. The bridge has overhanging sidewalks with paneled parapets. A steel guard rail has been added to the bridge. The approaches are earth fill.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: According to Condit, the first continuous-slab bridge in the United States was built in 1909 to carry Lafayette Avenue over the tracks of the Soo Line in St. Paul, Minnesota. The steady improvement of concrete-slab bridge designs and concrete-reinforcing systems led to their increasing adoption, especially for highway bridges. The NJ 44 bridge employs a common continuous slab design with piers consisting of longitudinal beams extending over rows of columns. A rarer design employs a single row of columns along the center line of the deck.

Railroads in New Jersey did not frequently build continuous slab bridges. No documentation has been located to explain why the Pennsylvania Railroad chose continuous slab construction over other more common bridge designs, e.g. steel girder. The continuous slab design appears to lend itself well to the pronounced skew of the crossing. The railroad also planned in the future to lay a second track under the bridge explaining the uneven placement of the bents and floor beams. The bridge is a good example of its type, but it is not historically or technologically distinguished, and better examples exist.

SETTING / CONTEXT The two-lane bridge is located on one of the main thoroughfares leading into downtown Swedesboro. Raccoon Creek is a wide slow-moving, tree-lined river with frequent fishing holes along its banks. To the south is a residential neighborhood (c. 1800-1990) with an intermixture of small businesses.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete-encased steel stringer with pierced balustrade and reinforced-concrete substructure is one of four similar bridges built by Gloucester County between 1933 and 1942. Edward H. Ellis of Westville contracted to construct the bridge. Concrete-encased stringers are a common bridge type throughout New Jersey and since 1920 have been widely used by the state and county highway departments. The bridge is not historically or technologically distinguished.

SETTING / CONTEXT The Locke Avenue Bridge, the furthest upstream of three movable spans across Raccoon Creek between the Delaware River and Swedesboro, last opened to river traffic in the mid-1960s. A working-class neighborhood of two-story, two-family houses is located upstream on the southern river bank. Across the tree-lined northern bank, the land opens into farmers' fields. At the southern approach is the original tender's house.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 11/29/90, Letter 6/30/95.

SUMMARY The riveted-steel truss is the only swing span, and the oldest of three existing movable spans in Gloucester County. The center-bearing swing was one of the most common movable spans built in the 19th and early-20th centuries. Fabricated by the Owego Bridge Co. of Owego, NY, the hand-operated bridge has roller end lifts. Although no longer operable, the bridge possesses good historic integrity and documentation, and its neighborhood provides an appropriate context.

SETTING / CONTEXT The three-span pipe culvert crosses Mantua Creek at the Pitman Borough and Washington Township border. On the Pitman side of the border is a residential neighborhood (c. 1900-1980) and L. Arthur Walter Park, a city playground. On the Washington Township side of the border is a busy intersection with NJ 47, commercial properties, and an electric transformer station.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span culvert consists of standard corrugated steel pipes with earth backfill and stone and concrete rubble facing. According to county engineer's records, in 1940 a flood washed out an earlier concrete slab bridge, and the contractor apparently used the rubble to build the retaining walls for the culvert. Single and double pipe culverts such as this are common but usually fall below the 20' span limit. The culvert is not historically or technologically distinguished.

SETTING / CONTEXT The operating vertical lift bridge spans Mantua Creek on the northern edge of Paulsboro, once the principle Delaware River port in Gloucester County. Mantua Creek is a tidal estuary and is still frequently navigated seasonally by pleasure craft. On the north bank is a new operator's house (c.1988). To the south is Paulsboro's business district with a mixture of nineteenth and twentieth century structures without NR district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The vertical lift bridge has thru-girder deck, lattice-girder vertical towers with portal bracing and longitudinal lattice girders, wire-rope lift mechanism, reinforced-concrete counterweights in steel-plate frames, and operating machinery at the center of the span. The bridge is a distinguished and well-preserved example of a "Waddell-type" vertical lift, and is one of three such bridges built by the state in the county between 1935 and 1940. All are eligible.

INFOR MATION

SOURCES:

Pulver, H. E. "Vertical Lift Bridges," in George A. Hool and W. S. Kinne, eds., Movable and Long-Span Bridges. New York: McGraw-Hill, 1923.
Waddell, J. A. Bridge Engineering. New York: John Wiley & Sons, 1916.

PHYSICAL DESCRIPTION: The two-lane bridge is a single-span movable Waddell-type vertical lift with two encased steel stringer approach spans. Its overall length is 167' with a 40' roadway. The main vertical lift span consists of a single thru girder with floor beams. The span is constructed to permit it being lifted vertically to a height of 64' clear above mean low water. At each end of the main span are steel towers approximately 96'-high. Each tower consists of two legs with horizontal and diagonal sway bracing. Between the tops of the opposite towers pass two trusses, and suspended between the trusses is the central overhead machinery house. The towers and bracing are all riveted angles, channels, and beams steel construction. Cantilevered off both sides of the main span are concrete deck sidewalks with sheet metal balustrades. The main span is operable and tended.

Power for lifting the bridge is supplied from the central overhead machinery house that contains an electric motor and a back-up gas engine. At the top of each of the four tower legs are sheaves over which pass steel-wire ropes. The ropes are attached at one end to counterweights and at the other to couplings attached to the roadway. Power is transmitted from the motor to the sheave coupling by means of direct drive line shafting and gears. The span moves up and down along a C-shaped guide on the interior of the tower legs. The machinery is equipped with brakes, clutch, and locks. The two counterweights consist of concrete blocks held within riveted steel plate frames on the exterior side of the tower legs.

The approach spans are concrete encased steel stringers with concrete balustrades and sidewalks. The bridge has a concrete substructure with cutwater piers. The fenders are timber piling. At each end of the main span are safety gates original to the bridge construction. Additional modern safety gates have been added at the abutment ends of the approach spans. Northeast of the northern approach span is a modern two-story operator's house.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The vertical lift bridge across Mantua Creek is a well-preserved and operable example of a historically and technologically significant bridge type. The vertical lift type represented important advances in structural steel construction, and was an alternative to bascule and swing span type movable bridges. The Mantua Creek Bridge is one of three vertical lifts along old New Jersey Highway Route 44 in Salem and Gloucester Counties. All three bridges, built between 1935 and 1940, have been recommended as eligible because they represent an increasingly rare early 20th-century bridge type.

Vertical lift bridges are a special bridge type combining both mechanical and civil engineering technologies. The first vertical lift bridge of importance in the United States was designed by well-known bridge engineer, J. A. L. Waddell. In 1894 he oversaw the construction of the South Halsted Street Bridge over the Chicago River in Chicago, Illinois. The bridge, which had overhead trusses between the towers and sheaves at the top of each tower leg, became known as the Waddell-type vertical lift. Beginning in 1908 vertical lift bridges were built in increasing numbers, often replacing swing-span type movable bridges. According to bridge engineer H. E. Pulver (1923) the advantages of the vertical lift included simplicity of design, rigidity, reliability, ease of operation, short time of operation (usually 40-50 seconds), power economy, cost of operation, and less chance of collision with boats. The bridge type was particularly suitable to long span crossings where high navigational clearance was required.

The Mantua Creek Bridge was built in 1935 as part of the reconstruction of NJ Highway Route 44. No plans or records of the original construction have been located, however, plans from the other two existing vertical lift bridges suggest that the firm of Ash, Howard, Needles, and Tammen of New York and Kansas City probably acted as consulting engineers on the New Deal era public works project. The bridge survives with few significant alterations. In c.1985 the electric motors were rehabilitated and new brakes and locks added. The bridge still opens to navigation, mostly to pleasure craft in the summer.

The Mantua Creek Bridge is the oldest of the three bridges on old NJ Highway Route 44. The second oldest, US 130 over Oldmans Creek

(1710152), is nearly identical to the Mantua Creek Bridge. It is no longer operable but retains its original operator's house. The youngest bridge, US 130 over Raccoon Creek (0807151) is also operable. It is of different construction and has been retrofitted with machinery and a new operator's house. As a group the bridges are neither the oldest or largest of their type in the United States, however, they are significant engineering achievements representing the application of vertical lift bridge technology to medium-span crossings.

SETTING / CONTEXT The two-lane bridge spans a small creek in a rural section of South Harrison Township. Nearby are farmers' fields and homes on large wooded lots. Immediately adjacent to the bridge is a well-maintained house (c. 1950) with a generous yard.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The earth-filled, reinforced-concrete arch with plain concrete parapets is a representative example of over 15 other existing arches built by Gloucester County between 1912 and 1940. William C. Cattell, the county engineer from 1909 to 1942, preferred the parapet arches for the creek crossings in the hillier western sections of the county. An eligible example of the bridge type is located in the Mullica Hill Historic District (#0825150).

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge with plain concrete parapets is a representative example of over 20 existing short-span, parapet, concrete slab bridges built by Gloucester County between 1922 and 1941. Since 1920 concrete slab bridge designs have been popular because of their low cost, strength, durability, and ease of construction. An early example of a concrete slab bridge (#0809L02) has been recommended for National Register eligibility.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge with concrete parapets is one of the oldest and most complete examples of over 20 similar short reinforced-concrete slab bridges built by Gloucester County between 1922 and 1941. Slab bridges were often designed by county engineers like William C. Cattell to replace older bridges in the highway improvement campaigns of the 1920s and 1930s. The bridge is technologically significant within the county context and is one of the best examples of its type in the area.

"William C. Cattell Died Last Night at Wenonah Home." Woodbury Daily Times. Dec. 24, 1948.

PHYSICAL DESCRIPTION: The two-lane, 24'-long, 30'-wide, single-span concrete-slab bridge with parapets spans a shallow creek in rural Gloucester County. The slab reinforcing consists of ½", ¾" and 1" steel rebars. The abutments are reinforced concrete. According to the county engineer's records, the only alterations to the bridge have been resurfacing the roadway, and in 1983 sandblasting and painting. The cast-metal plaque on the inside of the parapet reads "William C. Cattell, County Engineer. George A. Charlesworth, Contractor."

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The bridge is an early example of over 20 similar concrete-slab bridges built by Gloucester County between 1922 and 1941. The bridge is technologically representative of the other concrete slabs in Gloucester County and has the solid parapets and decorative moldings characteristic of county engineer William C. Cattell's designs. The bridge is one of the best examples of a bridge type of local historical significance.

In Gloucester County and throughout rural New Jersey, concrete-slab bridges designed by professional county engineers rapidly replaced older bridges (often less durable timber stringers) in the highway improvement campaigns of the 1920s and 1930s. The slab bridge was an important link in the development of farm to market roads. Proponents hoped that better roads would end the cultural and social isolation of rural dwellers, and would provide a recreational outlet for automobile-owning city dwellers. The roads brought perishable goods, such as milk and vegetables, to the cities, and were one factor leading to the expansion of specialized agriculture in rural New Jersey.

Many county engineers adopted reinforced-concrete bridge construction not only because of its durability but because of the local availability of concrete, sand, and gravel. William C. Cattell (1867-1948), Gloucester County's engineer from 1909 to 1942, was the son of a farmer and received no formal engineering training except at the hands of a professor at a local private academy. At the age of 21, he entered into the business of surveying and civil engineering. Cattell was intimately involved with the professionalization of engineering; he became a member of the American Society of Civil Engineers, and was the first president of the New Jersey Society of Professional Engineers. Cattell appears to have followed the best engineering practice of his time, drawing up general specifications for the systematic improvement of Gloucester County's roads and bridges. By the 1920s Cattell had settled upon a concrete-arch design (0825150) for the hillier western sections of the county, and the concrete slab design for the flatter topography of the eastern part of the county. Through the agency of county engineers such as Cattell and county and state highway improvement campaigns, local contractors, like George A. Charlesworth of Elmer, learned the techniques of reinforced concrete construction. Charlesworth, and perhaps a dozen other local contractors, competed for the county bridge contracts through a bidding process overseen by the county engineer. Between 1922 and 1936 Charlesworth constructed 8 of the existing concrete-slab bridges in the county. Charlesworth built the Coles Mill Road Bridge at a price of $4675.

Although the wooded lots near the Coles Mill Road Bridge were probably open fields in the 1920s, the setting remains rural, speaking to the bridge's significance as a link on a country farm to market road. The Coles Mill Road runs east to west connecting the countryside with New Jersey State Highway Route 47 and the railroad depot at Coles.

DESIGNER/PATENT EDGEMOOR BRIDGE WORKS **BUILDER** DELAWARE CONSTRUCTION CO.

SETTING / CONTEXT The four-lane wide bridge spans Woodbury Creek at the northern end of downtown Woodbury. The bridge lies on the border of a large historic district that incorporates Woodbury's commercial and residential areas (c.1715-1941). A nomination has been submitted for review by ONJH. The bridge appears to be a contributing element, but is also historically and technologically significant in its own right.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Agreed Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Constructed in 1892, the single-span deck-girder with floor beams bridge with stone abutments and lattice railing is one of the earliest examples of steel girder construction in New Jersey. The bridge has four shallow girders with floor beams, stringers, and a corrugated plate deck that is now under steel flooring added in 1958. The bridge divides the older section of town from the newer development to the north and contributes to the proposed historic district.

INFORMATION

SOURCES:

Darnell, Victor. Directory of American Bridge Building Companies. Washington, DC: Society for Industrial Archeology, 1984.
New Jersey Department of Transportation. Bridge Plans 0810150, 1892-1958.
Office of New Jersey Heritage. Nomination for Woodbury Historic District, 1991.
Scharf, J. Thomas. History of Delaware, 1609-1888. Volume II. Philadelphia: L. J. Richards Co., 1888.

PHYSICAL DESCRIPTION: The single-span bridge is a multi deck girder and floor beam system with a 42'-span and 46'-roadway. On either side of the bridge are sidewalks with lattice railing. The bridge members consist of 4 built-up girders, 4'-depth, floor beams, and interior and exterior stringers. Original plans indicate all bridge members were constructed of steel. The bridge has been strengthened and some of the floor beams and stringers are modern additions. The bridge rests on coursed-ashlar abutments.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Broad Street Bridge is technologically significant as one of the earliest examples of steel-girder highway bridge construction in New Jersey. It was designed by a well-known fabricator, the Edgemoor Bridge Works of Delaware, at a time when steel was rapidly replacing iron as a structural material in bridges. In addition, the bridge lies on the proposed border of the Woodbury Historic District (c.1715-1941), and makes a significant contribution to the historic character of the neighborhood. A nomination has been submitted for review by ONJH. The large district, located to the south of the bridge, incorporates portions of Woodbury's commercial and residential areas. The bridge with its distinctive lattice railing visually divides the older section of town from the newer development to the north. The bridge spans Woodbury Creek at its furthest navigable point, and the area adjacent the bridge was once an industrial center with mills and warehouses, and a point for export downstream to the Delaware River.

In 1892 the Edgemoor Bridge Works of Edgemoor, Delaware, received the sub-contract to design and fabricate the Broad Street Bridge for the Delaware Construction Company. Organized in 1869 by William Sellers, the Edgemoor Bridge Works was one of the nation's largest builders of highway and railroad bridges. Among the noteworthy bridges constructed by the company were the East River Bridge between New York and Brooklyn, the Schuylkill and Susquehanna River Bridges for the Pennsylvania Railroad, and the crossing of the Missouri River between Omaha, Nebraska, and Council Bluffs, Iowa. In the late-19th century the Edgemoor Bridge Works' shops were considered some of the most complete and up-to-date in the nation. The company employed between 500 and 800 workers, most of whom lived in the company town of Edgemoor. The Broad Street Bridge is one of the earliest surviving examples of the company's work in New Jersey.

The bridge deck and floor beam system have been strengthened twice in the last one hundred years, but the bridge retains its overall integrity of design. In 1922, shortly after the State Highway Department took over Broad Street as part of State Highway Route 6, new stringers and floor beams were added to the bridge. In 1953 a new deck and roadway was constructed above the existing corrugated plate, and some repairs and changes were made to the stringers and floor beams. The original 1892 plans show a fancy railing different from the one now on the bridge. The original plans specify a "Carnegie Hand Rail," however the current lattice railing was manufactured by the Lyon's Iron Works. It is not known whether the current railing was added after the bridge construction, or if perhaps a change was made from the original plans at the time of construction.

CONSTRUCTION DT 1939 (c1980) **ALTERATION DT** **SOURCE** MARKER

DESIGNER/PATENT WILLIAM C. CATTELL, CO. ENG. **BUILDER** JOSEPH W. ROGERS

SETTING / CONTEXT The two-lane bridge crosses the spillway at privately-owned Iona Lake. A box-shaped spillway/dam extends between the upstream abutments and a concrete slab extends from the bridge at deck level to help support the water-control gates. The approaches form the earthen retaining wall for the lake. Summer homes and residences (c. 1920-50) line the 3/5-mile long lake. The structural association of bridges and dams is common in the region.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge with concrete parapets is an example of over 20 similar short-span, parapet, concrete slab bridges built by Gloucester County between 1922 and 1941. Since 1920 concrete slab bridge designs have been popular because of their low cost, strength, durability, and ease of construction. The bridge is in fair condition although it has been sprayed with gunite (c. 1980). An early example of a concrete slab bridge (#0809L02) has been recommended for eligibility.

DESIGNER/PATENT NJ STATE HIGHWAY DEPT **BUILDER** UNKNOWN

SETTING / CONTEXT The four-lane, six-span bridge crosses Big Timber Creek about 3/4 mile upstream from the Delaware River. The surrounding area is heavily developed with a mixture of commercial buildings and warehouses (c. 1900) near the river. Upstream is a small marina with docks for pleasure craft.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 6-span bridge is composed of a thru girder main span and encased stringer approaches. It is supported on concrete piers and abutments, and it has concrete balustrades. The road was improved as part of the Camden Extension in the late 1920s, but the new bridge, which replaced a swing span, was not completed until 1934. The State Hwy. Dept. designed several girder bridges for longer crossings, and although not common, the bridge is not historically or technologically significant.

INFORMATION

SOURCES:
New Jersey Department of Transportation. Bridge Plans 0815152. 1934.

PHYSICAL DESCRIPTION: The four-lane, six-span bridge has a thru girder with floor beams main span and 5 encased stringer approach spans, three to the north and two to the south. The main span has a sheet-metal balustrade and cantilevered sidewalks. The approach spans have concrete balustrades and sidewalks. Beam guide rails have been added to the interior of the thru girders and between the sidewalks and the roadway of the approach spans. The bridge is supported on concrete piers and abutments. Wood fenders protect the main channel piers.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The bridge is an undistinguished example of thru girder and steel-stringer construction using period technology. The New Jersey State Highway Department often chose girders for longer crossings, and the bridge type is standard, although not as frequently seen as some other State Highway Department bridge types. The road was improved as part of the Camden Extension in the late 1920s, but the new bridge, which replaced a movable span, was not completed until 1934.

DESIGNER/PATENT ASH, HOWARD, NEEDLES & TAMMEN **BUILDER** UNKNOWN

SETTING / CONTEXT The four-lane, heavily-skewed, vertical-lift bridge spans Raccoon Creek on the southern edge of Bridgeport near the Commodore Barry Bridge to Chester, PA. The bridge is the furthest downstream of three movable bridges across Raccoon Creek and is still operable. On the northern bank is a modern, two-story operator's house (c. 1988) neighboring a number of small residences and businesses (c. 1830-1950).

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed vertical lift bridge has a thru-girder moveable span, built-up towers with portal bracing and longitudinal girders, concrete counterweights with steel-plate frames, and a steel grate deck. It is a distinguished and well-preserved example of a "Waddell-type" vertical lift. The bridge is the largest and newest of three vertical lifts built by the state in the county between 1935-1940. All are eligible. The tender's shanty was replaced in 1988.

INFORMATION

SOURCES:
New Jersey State Highway Commission, Division of Bridges, Raccoon Creek Bridge Plans, 1938.
Pulver, H. E. "Vertical Lift Bridges," in George A. Hool and W. S. Kinne, eds., Movable and Long-Span Bridges. New York: McGraw-Hill, 1923.
Waddell, J. A. Bridge Engineering. New York: John Wiley & Sons, 1916.

PHYSICAL DESCRIPTION: The four-lane bridge is a single-span movable Waddell-type vertical lift with four encased steel stringer approach spans. Its overall length is 285' with a 52' roadway. The main vertical lift span, which is skewed, consists of a single, 93'-long toe-to-toe, thru girder with floor beams. The span is constructed to permit it being lifted vertically to a height of 64' clear above mean low water. At each end of the main span are steel towers approximately 95'-high. Each tower consists of two built-up girder legs with horizontal and diagonal sway bracing. Between the tops of the opposite towers pass two girders, and suspended between the girders is the central overhead machinery house. Cantilevered off both sides of the main span are concrete deck sidewalks with sheet metal balustrades. The main span is operable.

Power for lifting the bridge is supplied from the central overhead machinery house that contains an electric motor and a back-up gas engine. At the top of each of the four tower legs are sheaves over which pass steel-wire ropes. The ropes are attached at one end to counterweights and at the other to couplings attached to the roadway. Power is transmitted from the motor to the sheave coupling by means of direct drive line shafting and gears. The span moves up and down along a C-shaped guide on the interior of the tower legs. The machinery is equipped with brakes, clutch, and locks. The two counterweights consist of concrete blocks held within riveted steel plate frames on the exterior side of the tower legs.

The approach spans are concrete encased steel stringers with concrete balustrades and sidewalks. There are four approach spans, two to the north and two to the south of the main span. The bridge has a concrete substructure with cutwater piers. The fenders are timber piling. At each end of the main span are safety gates original to the bridge construction. Additional modern safety gates have been added at the abutment ends of the approach spans. Northeast of the northern approach span is a modern two-story operator's house.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The vertical lift bridge across Raccoon Creek is a well-preserved and operable example of a historically and technologically significant bridge type. The vertical lift type represented important advances in structural steel construction, and was an alternative to bascule and swing span type movable bridges. The Raccoon Creek Bridge is one of three vertical lifts along old New Jersey Highway Route 44 in Salem and Gloucester Counties. All three bridges, built between 1935 and 1940, have been recommended as eligible because they represent an increasingly rare early 20th-century bridge type.

Vertical lift bridges are a special bridge type combining both mechanical and civil engineering technologies. The first vertical lift bridge of importance in the United States was designed by well-known bridge engineer, J. A. L. Waddell. In 1894 he oversaw the construction of the South Halsted Street Bridge over the Chicago River in Chicago, Illinois. The bridge, which had overhead trusses between the towers and sheaves at the top of each tower leg, became known as the Waddell-type vertical lift. Beginning in 1908 vertical lift bridges were built in increasing numbers, often replacing swing-span type movable bridges. According to bridge engineer H. E. Pulver (1923) the advantages of the vertical lift included simplicity of design, rigidity, reliability, ease of operation, short time of operation (usually 40-50 seconds), power economy, cost of operation, and less chance of collision with boats. The bridge type was particularly suitable to long span crossings where high navigational clearance was required.

The Raccoon Creek Bridge was built in 1940 as part of the reconstruction of NJ Highway Route 44. The firm of Ash, Howard, Needles, and Tammen of New York and Kansas City acted as consulting engineers on the New Deal public works project. The bridge survives with few significant alterations. In c.1985 the electric motors were rehabilitated and locking mechanism added. As well, a new operator's house was constructed on the Bridgeport side of the creek. The original operator's house and dwelling, which plans show on the opposite bank of the creek, have been demolished. The bridge still opens to navigation, mostly to pleasure craft in the summer. At one time Raccoon Creek was navigable upstream to Swedesboro, which was a shipping point for lumber and fresh produce.

November 12, 2002

The Raccoon Creek Bridge is the youngest of the three bridges on old NJ Highway Route 44. It differs from the other two in that it is skewed; it has a 4-lane roadway instead of a 2-lane; and, it has tower legs and bracing of built-up girders rather than riveted angle, channel, and beam columns and trusses. The oldest vertical lift bridge, NJ 44 over Mantua Creek in Paulsboro (0806150), is still operable and has been outfitted with new operating machinery and operator's house. The second oldest bridge, US 130 over Oldmans Creek (1710152) is no longer operable, but retains its original operator's house. As a group the bridges are neither the oldest or largest of their type in the United States, however, they are significant engineering achievements representing the application of vertical lift bridge technology to medium-span crossings.

SETTING / CONTEXT The four-lane, three-span bridge crosses Big Timber Creek between Gloucester and Camden Counties. The surrounding area is heavily developed with commercial warehouses (c. 1900), small businesses, and restaurants near the river, and residential neighborhoods (c. 1830-1950) lying off side streets. The bridge spans the creek about 1/2 mile upstream from the Delaware River.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The three-span bridge has a deck girder main span and steel stringer approaches. The main span rests on reinforced-concrete cutwater piers while the approach spans rest on separate concrete bents. According to NJDOT plans the bridge was originally built as a bascule designed by Hardesty and Hanover of New York. In 1977, the state built entirely new approach spans and fixed the moveable span in place, retaining only the girders, floor beams, and substructure.

DESIGNER/PATENT CENTRAL RAILROAD OF NEW JERSEY **BUILDER** UNKNOWN

SETTING / CONTEXT The heavily-skewed, two-lane, deck girder bridge spans a single track of the Millville Branch of Conrail near the western end of the village of Sewell. The immediately surrounding area is lightly wooded with scrub trees and heavy undergrowth. To the east is a residential neighborhood (c. 1920-80) and to the west a commercial warehouse (c. 1980).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The single-span, encased, deck-girder and floor beams bridge with a vaguely Moderne-styled reinforced-concrete substructure has paneled concrete parapets with vertical scoring and concrete wing walls with horizontal scoring. While not common, such detailing is not infrequent in the late 1930s. The bridge is technologically unexceptional. Better detailed railroad overpass bridges that are evaluated as eligible are located in Mercer and Camden counties.

INFOR MATION

SOURCES:
Ketchum, Milo S. The Design of Highway Bridges of Steel, Timber and Concrete. New York: McGraw-Hill, 1920.
New Jersey State Department of Transportation. Bridge Plans. 1937.

PHYSICAL DESCRIPTION: The 70'-foot long, 30'-wide, skewed, single-span, concrete-encased, deck-girder bridge survives with very few alterations. The paneled parapet walls carry an Art-Deco motif with vertical scoring and the concrete wing walls have been molded to appear like masonry. The concrete-encased girder fascia have horizontal scoring. The floor beams are also encased. Stone block pavers, probably original, can be seen in spots underneath the bridge's asphalt road surface.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: Many railroads, including the Central Railroad of New Jersey, frequently chose steel-girder bridges for their above grade crossings. Except for the distinguishing Art-Deco motif on the parapets, fascia, and wing walls, the Mantua Boulevard bridge is technologically unexceptional in comparison to other girders. Built in 1937, it is not an early example of concrete-encased girder construction. In Gloucester County, an older example of a concrete-encased girder, Hunter Street over Conrail (0802I14, c. 1914), has been recommended for contributing status in the proposed Woodbury Historic District.

SETTING / CONTEXT The bridge carries a 2-lane street over an old depressed road (now abandoned) that ran down the side of the Palisades. Originally known as Bowers St., it is paved with Belgian pavers, and a random-ashlar retaining wall holds back the cut. Bowers St. becomes Holland St. a short distance east of the bridge. The bridge is located in a late-19th century residential area, and there is a park on one side.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The handsome, well-detailed concrete arch bridge is finished with a stone veneer. It has radiating limestone voussiors and a keystone incised with the "1905" date. The iron lattice railing is also original. The bridge was designed in 1905 by T.H. McCann, an engineer from Hoboken. While the plans do not indicate the use of reinforcing bars, the shape of the arch suggests that it is one of the earliest surviving reinforced concrete spans in the county.

DESIGNER/PATENT **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is in an undistinguished late 19th-century urban residential neighborhood. It carries a wide city street over now-abandoned 1869 cut built for the CNJ RR's Newark & New York Branch (later ConRail's West Side Avenue Branch). The railroad right-of-way is not maintained.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge consists of 4 open web, triple-intersection deck girders with lateral bracing supported on ashlar abutments that probably predate this span. The flooring system with a concrete deck on rolled transverse beams is not original. The cantilevered sidewalks have metal picket railings. Information on when and by whom the bridge was constructed was not located, but stylistically its appears to be ca. 1890. A rare example of an early open web girder span, it is technologically significant.

INFORMATION

Bibliography:
Schmidt, W.H. "Costliest Railroad Now Half Abandoned." Trains Magazine. November, 1948. NJDOT. Plan File.

Physical Description: The deck girder bridge consists of four triple-intersection or lattice open web girders supported on low masonry abutments resting on the solid rock walls of the railroad cut. The web diagonals are cast or rolled wrought-iron T-sections set back-to-back. The flanges are built up with plate and angles. The present flooring system is replacement, and it consists of rolled transverse beams and a concrete deck. The lateral braces set between the girders are angles, and they may also be an addition. The bridge has a cantilevered sidewalk enclosed by a metal railing that appears to date stylistically to 1913. The date attribution is based on stylistic similarities with the Ocean Avenue bridge (0950163).

Historical and Technological Significance: When the wrought-iron lattice-web deck girder bridge was fabricated has not been verified (no plans are on file with NJDOT, and the SI&A sheet indicates that no plans are available from Conrail), but stylistically it dates to at least ca. 1890. It is very similar to a lattice-web bridge over the same rail line at Ocean Avenue in Jersey City (0950163). The date of construction of the Ocean Avenue bridge is also unknown. This span is technologically significant as because it is a rare and well-preserved survivor of an early overpass bridge type, and it has the unusual T-section members. Several other examples of the T-section have been identified on late-19th century railroad bridges in the northern half of the state as well as on the Ocean Avenue span, but the detail is so rare and so early, that all spans with it have been evaluated as technologically significant.

The Bergen Avenue bridge carries a city street over a mile-long double-track cut built in 1869 for the Newark & New York Railroad through Bergen Hill, a long ridge separating the waterfront of Hudson County from the land to the west. The Newark & New York Railroad was built to give the shortest, fastest route between Newark and the Central Railroad of New Jersey (CNJ) ferry terminal at Communipaw. The line was built for and operated by the CNJ. In the 1920s, 38 daily local passenger trains traversed this route, which serviced four passenger stations in its mile-long roadway through Jersey City. Passenger service ended in 1948, and the line was single-tracked and used for freight only (Trains, p. 52). When Conrail took over the CNJ's property in 1967, the line became known as the West Side Avenue Branch. It was abandoned by Conrail in the mid-1980s.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge is located among undistinguished 20th century row houses and commercial buildings. It carries an important city street over a deep railroad cut created prior to 1874; the cut was widened to allow double tracking of the railroad in 1896. The bridge is named Jones Memorial Bridge, and was dedicated to the memory of Kearny Mayor Arthur H. Jones in 1938.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span built-up deck plate girder bridge composed of 2 sets of girders with floor beams is supported on built-up steel bents. It has concrete balustrades with rectangular piercing. Of greater historic significance is the railroad cut the bridge crosses which was a branch of the former Delaware, Lackawanna & Western RR. The present bridge, which is not technologically innovative, is more recent than the late-19th century cut, and is thus not historically associated with the railroad.

DESIGNER/PATENT WADDELL & HARDESTY (1938) **BUILDER** UNKNOWN

SETTING / CONTEXT The viaduct carries a four-lane street from the low-lying land of Hoboken up the side of Bergen Hill (also known as the Palisades) to the Jersey City Heights neighborhood. Under the viaduct are parking lots and undistinguished 20th-century industrial structures, as well as ConRail's River Line. At its foot, at the east end, is a group of 19th-century commercial structures with historic district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The long, 31-span bridge consists of 2 Warren deck truss spans, 27 deck girder spans, and 2 stringer spans supported on steel bents that were strengthened in 1938 and concrete abutments. The truss bearings and footings were also upgraded in 1938. While the spans themselves are not technologically innovative, the structure as a whole is impressive given its size, date of construction, and state of preservation. It was rehabilitated again in 1987, the year the roadway was widened.

INFOR MATION

Bibliography:
Hudson County Engineer Office: Bridge File.

Physical Description: The viaduct consists of 31 span; 2 are Warren deck trusses, 27 are built-up deck girders, and 2 are steel stringers. It is supported on steel bents, some on concrete plinths, and concrete piers and abutments. The trusses have hinged bearings. Most of the bents are composed of four built-up steel columns with heavy lateral bracing. One bent that was rehabilitated in 1983 has only two columns that rest on heavy steel girders that distribute the load. In 1938 the viaduct was rehabilitated and strengthened by the addition of new floor beams, heavier bents and new footings, and lateral bracing. That rehab was done after plans prepared by Waddell & Hardesty. In 1987 A. G. Lichtenstein prepared plans for another rehabilitation that included changing the way the previously canted bearings work and conversion of one sidewalk to part of the roadway. Both rehabilitations were sensitive to the original design of the structure.

Historical and Technological Significance: The 31-span viaduct was originally built in 1910, and it forms an important route from Hoboken up the Bergen Hill to Jersey City. Bergen Hill, also called the Palisades, is a mile-wide ridge that runs parallel to the Hudson River for many miles. The approximately mile-square town of Hoboken lies between the ridge and the river. Because the east side of the hill is a steep cliff about 100' high, access from Hoboken to Jersey City was limited. At the south end of Hoboken there are old roads that scale the hill, but at the north end, there were none until the 14th Street viaduct was completed in 1910. Thus, in addition to its local historical significance, the viaduct is an impressive engineering solution to a difficult transportation problem, and it utilizes a variety of bridge types ion that solution. It is technologically significant. The 1938 strengthening and rehabilitation was designed by the noted consulting engineer firm of Waddell & Hardesty.

CONSTRUCTION DT 1911 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a two-lane road over a 2-lane city street that divides a small urban park in two. The park is landscaped in the traditional Olmsted fashion, with trees on rolling grassy hills. It was completed by the Hudson County Park Commission in 1911, with Charles Lowrie as landscape architect. Just outside this area of the park are undistinguished 1920s apartment buildings.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Potential Park Historic District. May contribute.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge is significant as a contributing element to an early 20th century park. It is an impressive example of a concrete-arch park bridge and does not attempt to imitate stone masonry. Its decoration consists of a concrete balustrade with oval piercing and geometric colored tiles on its pylons. It is an elliptical barrel arch with solid spandrel walls, and is essentially unaltered. West Hudson Park appears to be a potential historic district because of its design and local civic history.

INFOR MATION

Bibliography:
Hudson County Park Commission. Second Report of the Hudson County Park Commission (covering June 23,1908-November 30, 1910). Jersey City Publishing Company.
Hudson County Engineers Office: Plan Files.

Physical Description: The handsome, well-preserved bridge is a simple elliptical reinforced concrete arch span with graceful, attenuated proportions. Its adornment consists of low balustrades with oval piercing flanking the 22'-7" wide roadway. Faience tile accents the plain posts. The wingwalls are topped by balustrades that match those used on the main span. The bridge appears unaltered.

Historical and Technological Significance: The 1911 bridge is a contributing element in a well-preserved, historically significant park that was designed by landscape architect Charles Lowrie. The span is not technologically innovative for its time, but it is representative of the high-quality, well detailed designs the plastic qualities of concrete afforded. The bridge is located in informally landscaped West Hudson Park, one of five county parks established by the Hudson County Park Commission about 1909. It was completed in 1911. Landscape architect Lowrie's description of West Hudson Park emphasized its woodland scenery, viewpoints, and the opportunity to create a picturesque lake out of several ponds already on the site. Because the park was long and narrow, Lowrie felt a direct driveway through it was essential to give access between the different sections. At the same time it was necessary to provide a transverse street, which is Davis Avenue, the road the bridge crosses. To keep Davis Avenue from disrupting the park, the park road was made to cross it. No plans for the bridge were located, so it is not known who designed the handsome arch bridge.

West Hudson Park ranks with Bayonne Park (completed about 1916) as the two most noteworthy of the original five parks. Both were important civic projects, and both retain their original planting schemes to a large extent. They also share a common design element of having bridges as prominent landscape features. Another bridge in West Hudson Park that was an original feature was rebuilt in 1991-1992. It no longer retains its historic design, so it is not a contributing resource (0900019).

SETTING / CONTEXT The bridge carries a two-lane park road over a paved footpath in the pastoral landscape of a large park completed by the Hudson County Park Commission in 1916. It was landscaped by architect Charles Lowrie. Bayonne Park is one of the five major Hudson County parks constructed as part of the City Beautiful movement of the early 20th century.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Park Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The bridge is a representative example of an early 20th century concrete arch bridge, designed as an integral element of the landscaping plan for a large urban park in the Olmsted tradition. It is an elliptical arch with solid spandrels and quatrefoil-pierced balustrades. The well-preserved county park is historically significant as part of an ambitious 5-park project from the 1910s. The bridge is not individually eligible for listing in the National Register, but would be a contributing element of an urban park historic district or a County - Wide Park Multiple Property listing should either of those be defined in the future.

INFOR MATION

Bibliography:

Second Report of the Hudson County Park Commission. 1910 (covering the period from June 23, 1908-November 30, 1910). Jersey City Printing Company.

Physical Description: The well-proportioned pedestrian bridge is an elliptical, closed spandrel, reinforced concrete arch bridge 24' long and 30' wide. Its decoration consists chiefly of the gracefully curved top concrete parapets with quatrefoil-shaped pierced panels. The bridge is well preserved.

Historical and Technological Significance: The handsome, well-proportioned 1916 reinforced concrete arch bridge is historically significant as an original element in a locally significant, picturesquely landscaped urban park. Bayonne Park, completed in 1916, is one of the five urban parks established about 1910 by the Hudson County Park Commission. It is one of two of those parks that was designed in the Olmsted style by landscape architect Charles Lowrie. The park is well preserved and is evaluated as significant because of its local civic and landscape architecture history. The bridge is an integral design element in the park, and it too is well preserved. No plans for the span were located, so the designer is not known. It is one of three concrete arch bridges in the potential historic district of Bayonne Park that were evaluated as contributing resources (0900023, 0900024).

Boundary Description and Justification: The bridge is located within an urban park that appears to have the history and integrity of original design to meet the criteria for inclusion in the National Register. Thus the bridge and its immediate setting are evaluated as significant.

SETTING / CONTEXT The bridge carries a major four-lane arterial highway over Amtrak's busy Northeast Corridor route from New York to Washington that was constructed circa 1905 and electrified circa 1935. The surrounding neighborhood is composed of undistinguished "strip" commercial and light industrial structures. To the east of the bridge is a patch of scrub woods. The rail line was originally built by the Pennsylvania RR.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased stringer bridge with a concrete substructure was built to upgrade Tonnele Ave. to become the US 1 approach to the George Washington Bridge, constructed 1927-1931. It is an example of the most common type of pre-World War II bridge in the state, and it is one of over 15 in Hudson County alone. It is not technologically innovative nor is the span of historical interest.

SUMMARY The concrete-encased stringer bridge with concrete balustrades and a concrete substructure is representative of many bridges designed and built by the state in the 1930s. The encasing was to protect the steel from deterioration. The span is undistinguished technologically and is without historic significance. It is one of over 15 stringer bridges in Hudson County.

INFOR MATION

Bibliography:
Annual Reports of the NJ State Highway Commission.
Freeman, Leslie E. : "The New Jersey Railroad and Transportation Company" in bulletin no. 88 of the Railway and Locomotive Historical Society, pp. 100-159. "Two heavy spans floated into place to complete Hackensack River bridges" in Engineering news - Record. Nov. 1, 1930, pp. 778-780.
"New Jersey State Highway Department Hackensack River Bridge Route No. 10", May 1929 bridge drawings in microfilm, 0904.

Physical Description: The 2169'-long bridge consists of a vertical lift span with several approach spans. The lift span towers are skewed. The approach spans consist of two camelback (Pratt) thru trusses, one modified thru Pratt truss span acting as a continuous span between its neighbors, a fixed tower truss span of modified Pratt form whose top chord rises from portal to tower face, a Pratt lift span with flat top chord, another fixed tower span, and five deck girder spans forming the west approach. The piers are reinforced concrete. The bridge, which originally carried a double line of trolley tracks, crosses the river at an angle, and the towers of the vertical lift are skewed to give maximum channel width.

The Pratt thru truss lift span has the lifting machinery and operator's house located on the lift span itself, with uphaul and downhaul cables going from the house to both towers. Compensation for the changing weight of the cable supported by the lift span consists of a heavy chain suspended from the counterweights and attached at its other end to the towers at about mid-height. As the span rises less and less of the chain is directly suspended from the counterweight, counterbalancing the additional weight of cable between the counterweight and the top sheaves.

Historical and Technological Significance: The Wittpenn Bridge, named for H. Otto Wittpenn, member of State Highway Commission 1929-1931, is a large and complete example of mid-20th century movable bridge technology that remains essentially in its original condition. Its design and construction required solution of a number of difficult engineering problems. One of only two road crossings of the Hackensack River west from Jersey City, it is located on the old Newark Turnpike, and the Belleville Turnpike, another old road, diverges north from the Newark Turnpike just west of the bridge. This route probably originally crossed the river as a ferry, but in 1790 a charter was given to "The Proprietors of the Bridges over the Rivers Hackensack and Passaic" to build a bridge at this location. The charter was bought out by the New Jersey Railroad & Transportation Co. in 1833 so that its tracks could share the bridge with the road. The bridge was rebuilt more than once, and was a wooden two span truss structure. In 1846 the railroad built a separate bridge, leaving the Turnpike alone to cross on the old bridge. In 1886 the Pennsylvania Railroad (successor to the New Jersey Railroad & Transportation Co.) built a second bridge so that it could use one for passenger trains and one for freight trains (Freeman, 1953). This arrangement remains to this day, though the bridges have been rebuilt since then.

The route across the bridge and on west via the Belleville Turnpike was designated as Route 10 (later changed to Route 7) in the 1927 expansion of state highways (Annual Report 1927, p. 403). Its purpose was to take traffic from Jersey City, including from the Holland Tunnel, west through Kearny, Harrison, northern Newark, and on west to intersect Rt 6 (now NJ 46) near Dover (Morris County). In the automobile age the traffic across this bridge increased greatly in the 1920s, although after 1932 it declined for a time, due to the opening of the Pulaski Skyway.

In 1926 the U.S. War Department required the NJ State Highway Department to replace the swing bridge in order to permit 35' vertical clearance when the bridge was in the closed position. This meant constructing a new bridge parallel to the old one so as not to block the highway during construction. The approaches also had to be raised to provide for the new, higher vertical clearance. In addition the channel was to be relocated to the easterly side of the river while the previous channel had been on the west side. This meant that the construction of the new bridge had to proceed without the spans over the old channel so the latter could continue in service while the new channel was being prepared. Those spans, which were deck girders, were floated into place over a weekend when the channels could be closed temporarily during the final phase of construction. At this time the old bridge's fixed spans over the new channel were removed (Eng. News-Record, pp. 778-780).

Meanwhile the Pennsylvania RR was also required to modify, its two bridges in the vicinity. An agreement was reached with the railroad

A. G. Lichtenstein & Associates, Inc. performed initial survery.

that one of the railroad bridges (carrying a freight line) would be built parallel and adjacent to the Highway bridge, and that to save on the cost one set of piers would be built to carry both bridges, the costs of the piers to be divided proportionately. The railroad followed essentially the same procedure for floating the new spans into place and removing the old spans, at the same time (Eng. News-Record, 778-780; Annual Report 1927, p. 403). The highway was opened for traffic on Nov. 5, 1930, and the previous bridge was removed (Annual Report, 1930, p. 480, 483).

W.J. Sloan was chief engineer for the State Highway Department, and he gave final approval to all plans for the bridge while Sigvald Johannesson was the "engineer of design," according to Engineering News-Record. Consulting engineers for the lift bridge portion were Harrington, Howard and Ash of Kansas City and New York. The firm was noted for its vertical lift bridges, and they designed many in the state built between 1925 and 1942. The contractor for the bridge superstructure (river spans and east approach) were Stroebel Steel Construction Co. (1929 AR, p. 527). It was fabricated by Mt. Vernon Bridge Co. (Ohio).

SETTING / CONTEXT The bridge takes an active Conrail industrial spur across US 1&9T, a busy arterial route, in an area of sprawling modern industrial plants and overgrown vacant land. A modern firehouse is to the northeast. It is the southernmost of two closely spaced spans that originally crossed the Morris Canal (abandoned in 1924 and subsequently drained and filled) as well as the eastbound lanes of US 1&9T.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2 simple span thru girder bridge with floor beams is supported on a concrete substructure and decorative concrete pylons at the girder ends. It has a ballasted deck. Not original to this location, the bridge was moved here for the rail spur which was built quickly to service the WW I federal shipyard. The yard has been redeveloped and does not retain its historic character. While the bridge has historical association with WW I, it is a an example of a common type and is distinguished.

INFOR MATION

Bibliography:
"Temporary bridge of old girders has suspended floor." Engineering News-Record. Vol. 81, pp. 538-39.
Parsons, Floyd W., ed: New Jersey: Life, Industries and Resources of a Great State. Newark, NJ: New Jersey State Chamber of Commerce, 1928.

Physical Description: The bridge consists of two thru riveted girder spans with a total span of 191 ft. The bridge is built for heavy railroad loads and has a ballasted deck. The pier and abutments are of concrete. The sides of the abutments continue up in concrete pylons about 6-8 ft. above the deck of the bridge; these four pylons serve no functional purpose and are decorative features unusual for a bridge carrying an industrial rail siding. The bridge is an apparently unaltered example of the thru girder type as built by and for a railroad. The bridge carries an industrial branch of the former Pennsylvania RR over what was then called the Lincoln Highway, now US 1&9T, a busy arterial highway. The surroundings were originally the open marshes of the Hackensack Meadows, but by this date these had been diked and filled to form a low-lying, largely vacant area.

Historical and Technological Significance: In 1917, U.S. Steel began the emergency construction of the Federal Shipbuilding Yard at Kearny, a 160-acre facility intended to produce large numbers of ocean-going cargo vessels to assist the war effort in WW I. The facility included a number of large brick buildings a few hundred feet south of the Lincoln Highway. Some of these buildings remain, but the facility, which achieved its historical significance during World War I, is not well preserved, and does not have the integrity to be evaluated as a potential historic district.

At the time the shipyard was under construction, the Morris Canal was still in limited use. In this area the canal had been constructed in 1836, and it ran along the south side of the Lincoln Highway. The southern span of the railroad bridge therefore had to be long enough to span the canal as well as the eastbound lanes of the highway. In 1922, the canal was officially abandoned, and not long thereafter it was filled in. Presently a billboard stands just east of the bridge in the filled-in canal bed. A casual observer would not be aware that the Canal was once here, and might therefore wonder why the bridge is so much longer than necessary to span the three eastbound highway lanes.

The Federal Shipbuilding Yard at Kearny was built quickly, and 30 vessels of 10,000 ton capacity were constructed in a short time (it performed the same function in WW II). The urgent measures that had to be undertaken by the United States following our entry into WW I in 1917 included the construction of large numbers of cargo vessels to replace those lost to German submarines, in order to ,convey quantities of war material and supplies to Europe.

Such a large industrial enterprise naturally required railroad service, both to provide construction materials for original construction of the shipyard and to supply it with raw materials for its operations. The Pennsylvania RR built a spur south from Meadows Yard in Kearny toward the shipyard. The spur had to bridge the Lincoln Highway to get access to the new ship yard. In order to complete the spur as quickly as possible, the railroad constructed a temporary bridge of 85' span with trestle approaches using, in an ingenious way, some old bridge girders it had. This bridge was to be replaced as soon as possible by a more permanent structure (the site and the temporary bridge are described in Engineering News-Record. 1918).

The present bridge was built after 1918, but almost certainly before 1924, the year the Morris Canal was officially abandoned. The girders of the new bridge, were not new but had been built by the American Bridge Co. in 1915, according to a plate mounted on the girders. It is not known how or where they were used before being incorporated into the present bridge. The thru girder bridge is not a technologically distinguished example of its type and is thus not individually noteworthy.

The bridge can be considered one of the last remnants of the Canal era in Hudson County, as when built it was made long enough to span the still existing Canal adjacent to the highway. The Federal Shipbuilding Yard is now closed, but south of it is a BASF chemical facility that still requires regular rail service using the bridge.

In summary, neither the site nor the structure appear to meet National Register criteria. The bridge is a representative example of a common type, and the shipyard does not retain its historic appearance, including the filling of the Morris Canal. Much of the site has been

redeveloped for modern industrial purposes.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The thru girder with floor beams bridge is composed of 5 girders on a concrete substructure, and it has a ballasted deck. Its design is typical of the period when thru girders were ubiquitously used for rail-carrying overpasses. The span is well preserved, but it is not technologically or historically distinguished. It is historically associated with the regional corridors that the state highway department designed and built to expedite access to the 1927-1931 Holland Tunnel.

SETTING / CONTEXT The bridge crosses a major navigable river in the Hackensack Meadows, while the east approaches are surrounded by an urban industrial district. It shares common piers with an adjacent railroad bridge of the same type built at the same time; all were built in response to a requirement to provide a minimum 35' vertical clearance when closed. It was named for Otto Wittpenn, member of the State Highway Commission, 1929-31.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Potential Hackensack River Bridges Historic District and Penn. Railroad Harsimus Branch Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The bridge is a major movable lift bridge which is especially impressive in the context of three such bridges. The vertical lift span is a skewed Parker truss, and the east approach spans are two camelback thru trusses and a modified Pratt thru truss span. Sources credit Stroebel Steel with building all the superstructure; Harrington, Howard & Ash with consulting on the movable span; Johanneson as design engineer. W.J. Sloan was chief engineer of the NJ State Highway Department. It is individually eligible for listing in the National Register of Historic Places under Criteria A and C, and may be a contributing element to two potentially eligible historic districts -- Hackensack River Bridges and Pennsylvania Railroad Harsimus Branch (Jersey City to Kearny). These districts would focus on transportation and bridge historic resources.

SETTING / CONTEXT The bridge carries Amtrak's high speed double track passenger railroad over NJ 7 in the midst of the Hackensack Meadows, with some undistinguished modern industrial structures among the reeds surrounding the bridge. The northernmost of the structure's two spans bridges the Jersey City water supply aqueduct.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Although built as part of the Pennsylvania RR's 1905-1910 extension to New York City via a "high line" over the Hackensack Meadows, the bridge is a representative example of a common type. It consists of a deck plate girders with floor beams and is supported on concrete abutments and pier with ashlar cap stones, a common ca. 1905 detail. The span appears to be in its original state, but the metal railing does not appear to date to 1907. The bridge is not technologically significant.

INFOR MATION

Bibliography:
Temple, E.B. "The New York Tunnel Extension of the Pennsylvania RR Meadows Division and Harrison Transfer Yard." Transactions of the American Society of Civil Engineers. Vol. 68 (1909), pp.75-90.

Physical Description: The 2-span built-up deck girder with built-up floor beams bridge carries Amtrak's electrified double-track Northeast Corridor line toward the tunnels under the Hudson River. It is supported on concrete abutments with stone caps. The abutments were built wide enough for more sets of girders, but the were never added. The deck is ballasted and is enclosed by low pipe railings affixed to the top flanges of the girders. The span appears unaltered, and it has no distinguishing details.

Historical and Technological Significance: The technologically undistinguished built-up deck plate girder bridge was built in 1907 as part of the development of the Pennsylvania Railroad's New York Extension project. One of the largest and most costly construction projects ever undertaken by a private company, the project, part of the development of Pennsylvania Station, consisted of an elevated double-track line from Harrison across the Jersey Meadows to Bergen Hill (the Palisades) and then under the Hudson river to the massive new through station being built in Manhattan. The extension line then continued under Manhattan and the East River to a large new passenger station train-servicing yard on Long Island. The line is still in operation and is part of the busiest and most significant passenger rail corridor on the East Coast.

Despite its historical association with the development of the line and its continued use, the span and most sections of the right-of-way are not technologically significant. While there are some technologically distinguished features to the New York Extension, like the subaqueous tunnels and the subterranean right-of-way in Manhattan, this stretch of road and the bridge over NJ 7 are not. The bridge is a representative example of a common bridge type and design.

The basis for the 1935 date of construction assigned to the span by NJDOT is unknown. The span was designed by the Pennsylvania Railroad Office of Engineer of Bridges and Buildings. H. R. Leonard signed the plans which are dated 1907. The Pennsylvania Steel Company was the fabricator (bridge plaque).

DESIGNER/PATENT PORT OF NEW YORK AUTHORITY **BUILDER** AMERICAN BRIDGE COMPANY

SETTING / CONTEXT The bridge is at the edge of the Hackensack Meadows that is crisscrossed with interconnecting highways. It carries the approach from the west toward the Lincoln Tunnel, taking traffic from the Meadows level up to a cut through Bergen Hill. This viaduct is an integral part of the Lincoln Tunnel approach route built in the late 1930s, a historic and vital artery in the region's highway transportation network.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95 11/17/99.

SUMMARY The bridge consists of nine deck plate girder spans, two of which include cantilevered sections. The longer spans have haunched girders. The bents are rigid frame steel arches. The structure was widened in 1956, but the original design is well preserved, and it is an eligible resource as an innovative design to the problem of carrying an important traffic artery from one general level (the Hackensack Meadows) to another (the surface of Bergen Hill, also known as the Palisades).

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.
Dunham, Clarence. "Viaduct Approach to Lincoln Tunnel," Engineering News-Record. Vol. 124 (20 Feb. 1940), pp. 311-314.

Physical Description: The viaduct consists of a 1,152,,-long straight section and a 2-lane ramp at the east end and a curved ramp off the north side near the center of the span. Clarence Dunham, one of the engineers who helped design and build the viaduct, called it "an unusual structure and a rather striking departure from the types of viaduct that have been used in the past" (Dunham, p. 41). According to him the reason for its unusual design was twofold: toe foundations could not be designed for heavy loads, and at the same time it was desired to "give the most pleasing aesthetic effect possible" (Ibid.).

Most of the viaduct was to rest on the clay of the Jersey Meadows, which was not suitable for heavy foundations unless they were supported on piles or caissons going down to rock. Instead the engineers chose to use the lightest practical type of construction, with relatively long spans. Where rock was less than 50' from the surface at the easterly end of the viaduct, the foundations went down to rock. Elsewhere they were supported on piles. It was expected that differential settlement would occur under the piles, and the western abutment. Intermediate piers and the superstructure itself were carefully designed so the bridge would not be endangered by possible movements of the foundations, and adjustments were allowed for the expected settlement of the embankment connecting to the viaduct at its western end.

The viaduct is a series of spans combining continuous rigid frame and simple beam spans, all composed of deck girders. These are not of constant depth but rather vary according to the bending moment; they have curved bottom flanges which are deepest at the joints with the piers. This was done both for technical reasons and for a graceful appearance, according to Dunham. In the two rigid frames the pier legs are securely fastened to the deck girders between the rigid frames are suspended spans. The other piers are arranged in one of two ways: either as two-hinged bents or with a fixed top connection (to the adjacent deck girders) but with a hinge at the bottom. The piers that are part of the rigid frames are also hinged at their bases (Dunham, p. 41-43).

In addition to the main viaduct, the structure includes two off-ramps, one forming three quarters of a circle as it descends toward southbound Route 1.

Aesthetic considerations in the design of the viaduct include emphasis of the flanges of the girders by use of a secondary angle on the outside web of the exterior girders, giving appearance of deep, wide chords instead of a plain girder. Also, the legs of the piers are tapered from B" at top to 2' at bottom. This together with their flanges and the vertical angles at their centers are intended to give them pleasing lines. Another contribution to pleasing lines is the replacement of cross-bracing with portal bracing, which has double webs and diaphragms for torsional resistance (Dunham, p. 42).

An extra lane has been added in each direction in 1956, the time the third tube was being added to the Lincoln Tunnel. The exit ramps from the north side prevented expanding in that direction, so all the space was added on the south side, where an additional leg was added south of each pier to support an additional girder along the south side, braced to the original external girder. In addition, new floor beams were added with great cantilevered overhang on the east side, giving additional space. The sidewalks were modified as well. Efforts were made during the reconstruction to maintain the original appearances of the structure. The deck was reconstructed in the mid- to late-1980s.

Historical and Technological Significance: The viaduct is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). Technologically the viaduct is a significant engineering solution of a difficult problem of carrying an important traffic artery over the soft Jersey Meadows up to the level of Bergen Hill. It was done in a successful and visually pleasing manner. The road itself is also technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It

was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is individually distinguished as well as a contributing resource to the potential historic route (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

SETTING / CONTEXT The bridge carries a pedestrian walkway over NJ 495 and its surface approach ramps. NJ-495 is the divided six-lane highway approach to the Lincoln Tunnel. To the north and south of the bridge are modern, one-story structures.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-span stringer pedestrian overpass on concrete abutments and pier bents was constructed after NJ 495 was completed. Although the abutments have elements of the same Art Deco ornament used extensively on other bridges built as part of the late-1930s Lincoln Tunnel approach road, the superstructure itself and metal railing are plain, and they do not resemble the other steel bridges on the corridor. It is thus evaluated as a noncontributing resource to the Lincoln Tunnel approach road.

SETTING / CONTEXT The bridge carries part of the intermediate level of an unusual 3-level interchange between a local street and a depressed section of the Lincoln Tunnel approach road. The intermediate level serves as a kind of circle for vehicles changing from one road to another. The bridge carries a ramp over NJ 495, as does the identical span (0915155) to which it is connected via short roadways built on bedrock.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The 2-span rigid frame bridge with scored exposed concrete and stone-faced concrete wingwalls is detailed like other bridges on the corridor designed and built for the Port of New York Authority in 1938 as the approach to the Lincoln Tunnel. The bridge is significant as part of an innovative 3-level grade separation structure, with turning lanes forming a traffic circle located vertically between intersecting roadways, that accommodates both through and local traffic. It is well preserved.

INFORMATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The bridge is a 2-span reinforced concrete rigid frame. It is one of eight similarly detailed rigid frame spans on the limited access highway, and it is finished with a random ashlar stone veneer on the abutments, granite facing on the fascia and the ends of the pier, scored exposed concrete and pipe railings in an Art Moderne style on the parapets. The pedestrian fence is a recent addition. The bridge is well preserved.

Historical and Technological Significance: The rigid frame bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The 2-span rigid frame bridge with a sleek metal railing is finished with scoring in the exposed concrete and dressed stone facing on the concrete wingwalls that is common to all spans on the roadway, designed and built by the Port Authority to access the 1937 Lincoln Tunnel. The bridge is part of an unusual grade separation design where turning lanes form part of a traffic circle located vertically between the intersecting arteries. It is technologically and historically significant.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The bridge is a 2-span reinforced concrete rigid frame. It is part of a three-level bridge. The bridge carries the southbound part of the intermediate level of an unusual type of grade separated traffic interchange between JFK Boulevard and NJ 495, the Lincoln Tunnel approach highway, in which the intermediate level serves as kind of circle for all vehicles making turns from one route to the other. It carries this traffic over NJ 495.

Examples of aesthetic considerations in building this bridge include cut stone facings on the abutments, granite facing on the fascia and the ends of the pier, and pipe railings in an Art Moderne style on the parapets. It is detailed in the same mode as the eight other rigid frame spans on the limited-access highway.

Historical and Technological Significance: The rigid frame bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). SETTING / CONTEXT The bridge carries a wide, 2-lane city street over NJ 495, the six-lane highway approach to the Lincoln Tunnel. The limited access approach road was built through a congested 20th-century residential area in 1938, and it is a combination of open cuts and elevated sections. The route, old NJ 3, is a well-preserved and technologically significant engineering solution to mid-20th century highway development. It has district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The 2-span rigid frame bridge with a plain metal railing and stone-faced concrete wing walls is part of the late-1930s cut that carries the approach road to the Lincoln Tunnel through established areas. The span has the same Moderne detailing found on other bridges along the corridor. Exposed concrete is scored, and the stone veneer is crisp and devoid of embellishment which is in the sleek Modern taste. It is one of eight rigid frame overpasses on the technologically significant corridor.

INFORMATION

Bibliography:

Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The bridge is a 2-span reinforced concrete rigid frame. It is one of nine similarly detailed rigid frame spans on the limited access highway, and it is finished with a random ashlar stone veneer on the abutments, granite facing on the fascia and the ends of the pier, scored exposed concrete and pipe railings in an Art Moderne style on the parapets. The pedestrian fence is a recent addition. The bridge is well preserved.

Historical and Technological Significance: The rigid frame bridge, one of seven on the route, is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. It is one of eight similarly detailed rigid frame spans on the limited access highway, and it is finished with a random ashlar stone veneer on the abutments, granite facing on the fascia and the ends of the pier, scored exposed concrete and pipe railings in an Art Moderne style on the parapets. The pedestrian fence is a recent addition. The bridge is well preserved.

Historical and Technological Significance: The rigid frame bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

SETTING / CONTEXT The bridge structure carries a perpendicular 2-lane city street and a diagonally oriented city street plus two paved plazas over NJ 495, the six-lane highway approach to the Lincoln Tunnel. The limited access road the bridge crosses is located in a densely developed 20th-century residential area on the Palisades or Bergen Hill in Weehawken.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The oddly shaped 2-span rigid frame bridge of reinforced concrete has slab supported on concrete column extensions on each side to accommodate a diagonally crossing street. The extensions are finished with the same arched soffit and scored concrete as the rigid frame portion of the bridge. The wingwalls are faced with the same random-ashlar stone veneer as the rest of the 2.8-long limited access route. While not individually distinguished, the span is part of a historically significant route.

SETTING / CONTEXT The bridge carries a city street over NJ 495, the six lane highway approach to the Lincoln Tunnel. It is located in a mixed urban residential and commercial neighborhood with a variety of structures, ranging from an 1880s brick brewery a couple of blocks north to a modern used car lot, with row houses and tenements of all ages as well. The span is part of an open-cut corridor.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes
CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.
CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The 2-span rigid frame bridge has a plain metal railing and severe Moderne-style detailing to the concrete and stone facing on the concrete wing walls. While not individually significant, it is one of 8 rigid frame spans used on the Port Authority's approach to the 1937 Lincoln Tunnel. The bridge is well preserved, and it is detailed like other spans on the historic route, which relies on standard period bridge types crossing a deep open cut right-of-way through urban areas.

SETTING / CONTEXT The bridge carries a service road and sidewalks for NJ 495 over a busy avenue. It is part of the Lincoln Tunnel approach and is part of a 5-component structure that carries 3 levels of NJ 495 over Park Avenue. It is contiguous to 3800021 that takes eastbound traffic from S. Margin St. up to elevated NJ 495. The area around the structure is dominated by 20th-century townhouses and apartment buildings.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The well-detailed haunched deck girder with floor beams bridge is supported on a Moderne-style stone veneer concrete substructure. The concrete parapet is topped by a plain metal railing. The detailing is identical to other spans on the old Rt 3 approach to the 1937 Lincoln Tunnel. The 116'-long bridge is not technologically distinguished, but it is historically noteworthy as part of an important, well-preserved mid-20th century highway built in a developed setting.

INFOR MATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, (June, 1937), pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The deck girder bridge is the south-side, middle level of a 5-component, interconnecter span. This section, which carries a service road and ramp parallel to the limited-access portion of the route, is composed of a built-up deck girders with floor beams supported on concrete abutments with engaged bearing columns. The wingwalls are ashlar-faced to match the stonework used all along the route. The fascia girders are detailed with a geometric pattern to the stiffeners and a secondary flange to provide a shadow line. The outside girder is topped by a three-high metal railing. The span is contiguous to 3800021, and it, as well as the entire interconnected structure are well preserved.

Historical and Technological Significance: The deck girder bridge is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

SUMMARY A skewed haunched deck plate girder with built-up floor beams span is supported on engaged columns set into stone-faced concrete abutments. The nicely detailed girder is finished with a plain steel railing on the outside while the inside girder carries rolled section columns that support, in part, the rolled beam with stiffeners of 3800024, the parallel span. The bridge is an element in a 5-component 3-level structure. It is a contributing element to the technologically significant highway.

INFORMATION

Bibliography:
Ammann, O.H. "Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, (June, 1937), pp. 387-391.

SETTING / CONTEXT The bridge carries a local access service road that parallels an elevated section of NJ 495, the six-lane limited access approach highway to the Lincoln Tunnel, over vacant land. The viaduct is located on the south side of the elevated highway in a residential area dominated by 3-story row houses. The structure is a part of the historically and technologically significant roadway.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Not Individually Eligible. Rt 3 (I-495) Highway Approach to Lincoln Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Comments 11/17/99.

SUMMARY The reinforced concrete T-beams with a slab deck bridge is supported on concrete columns. Its south face is covered by a random ashlar stone veneer wall set with a flight of steps, and the north side is occupied by a viaduct that carries the ramp from S. Margin Street up to NJ 495. 0917164 is hardly discernible as a separate structure, but it is an original element in the development of the significant Lincoln Tunnel approach road and its interfacing with the existing urban street pattern.

INFOR MATION

Bibliography:
Ammann, O.H. 'Planning the Lincoln Tunnel Under the Hudson," Civil Engineering, 7, June, 1937, pp. 387-391.
Port Authority of New York. Annual Report. 1956.

Physical Description: The 4-span T-beam bridge with a slab deck is supported on concrete columns. It is a component of a 5 element structure that links local streets with an elevated limited-access highway. Its south face is covered by a random ashlar stone wall set with a flight of steps. The masonry matches that used all along the 1.5-mile long route. The original lamp standard is in place, but the luminaire is gone. The north side is occupied by a viaduct that carries a ramp from a local street up to the level of the limited-access highway. A modern flight of steps has been added to the west side of the structure.

Historical and Technological Significance: The T-beam viaduct is an original element of an approximately 2.8-mile long major transportation artery built 1938-1939 to serve as the main approach to the recently completed Lincoln Tunnel (first tube). The road is technologically and historically significant as a major engineering solution to building a highway that was both limited access and local through a congested area with significant geological considerations. The problem was solved in an innovative and aesthetic manner that retains its integrity of design and setting. It was designated Route 3 when built, and it became the heaviest-used single commuter line into the city, by virtue of serving the vast majority of the bus lines into New York City from the west. The structure is not individually distinguished, but it is a contributing resource to the potential historic route and thus has been evaluated as significant (Criterion C). Twenty-one structures were identified as being contributing resources along the right-of-way that stretches from US 1 & 9 to the Lincoln Tunnel.

The Palisades (called Bergen Hill locally) forms a ridge parallel to and just west of the Hudson River for several miles. The rock ridge is a barrier that must be crossed in some fashion by every transportation artery approaching New York City from the west in Bergen and Hudson counties. The oldest crossing of Bergen Hill is that now occupied by the PATH system and built by a predecessor of the Pennsylvania RR 1830-1834. The approach to the Lincoln Tunnel was the last major crossing of the Palisades (unless one counts the upgrading of the George Washington Bridge approaches in the 1960s). The Port of New York Authority built both the tunnel and the Route 3 New Jersey approach to the tunnel in close cooperation with state, county, and local officials. O.H. Ammann was the Director of Engineering on the project, and J.C. Evans served as Chief Engineer.

To get past Bergen Hill an open cut was decided upon, partly because it would be cheaper than a tunnel (which would require expensive equipment to remove exhaust gases), and also because local officials wanted the approach highway to be usable also as an arterial route across the ridge for local traffic. This decision required structures to carry the approach highway from the low meadows west of Bergen Hill up to the level of the cut through the Hill, and then back down to the tunnel mouth east of Bergen Hill. Major bridges were required for both of these tasks (Ammann, 391). In addition numerous bridges had to be built to take pre-existing local streets over the cut, and for the crossing of Hudson Boulevard (now JFK Boulevard) a very special type of grade separation structure was designed. The cut itself was, however, quite conventional, and most of the bridges were also conventional, if highly refined in their details (cut stone coverings for parts of their abutments, haunched fascia deck girders with patterned stiffeners, Art Moderne railings, and the like). When viewed as a whole, the entire roadway is a remarkable engineering accomplishment with visual cohesiveness achieved by repetition of bridge type and uniform Moderne detailing along the length of the project.

Boundary Description and Justification: The structure is one element of road development that is historically and technologically noteworthy. Because of the commonality of design, type, setting, and history that the structures on the route share and the state of preservation of the resource, the right-of-way of NJ 495 from the intersection with US 1 & 9 and the Lincoln Tunnel is evaluated as a potential historic district. This structure is along that right-of-way, so it is a contributing resource. The significant boundary is limited to the actual right-of-way between the aforementioned points.

DESIGNER/PATENT CNJ RR OFF OF CHIEF ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The setting consists of modernized single family homes and some 20th century apartment houses and small stores. The bridge crosses a deep cut through the city built in 1869 by the former Central RR of NJ as its Newark & New York Branch. This bridge is not the original bridge over the cut. The railroad is now abandoned and the cut is overgrown with brush and trees.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The bridge is composed of six rivet-connected open web deck girders supported on ashlar abutments with concrete caps. The outermost girders have verticals while the inside ones do not. The diagonals are composed of wrought iron T sections. The railings date to 1913 as does the flooring system and concrete abutment caps. The girders were in place in 1913, and they date stylistically to ca. 1890. They represent a rare and complete example of an early railroad overpass bridge type. The bridge is individually eligible for listing in the National Register of Historic Places under Criteria A and C.

INFOR MATION

Bibliography:
Schmidt, W.H.: "Costliest Railroad Now Half Abandoned." Trains Magazine. November 1948, p. 52.
Schreiber, Mike: "Hudson County Trolley Lines" in Branford Electric Railway Journal. Vol. 26, (March-April 1980), p.8.

Physical Description: Rusticated ashlar abutments with concrete caps added in 1913 support six ca. 1890 rivet-connected wrought iron Howe truss open web deck girders, each composed of a top and bottom flange joined with riveted connections by diagonal cast or rolled T-section members. The fascia girders have verticals, built up with an unusual spacer in the center, while the inside girders do not. The flooring system of rolled floor beams and a concrete deck were part of the 1913 reconditioning of the span. The cantilevered sidewalks with iron fence-like railings were also added in 1913. A trolley line ran across the bridge until about 1938 (Schreiber, p. 8). The bridge and ashlar abutments are well preserved.

Historical and Technological Significance: When the rare wrought iron lattice deck girder bridge was constructed is not known, but it was in place in 1913, the year the structure was "reconditioned" by the Central Railroad of New Jersey (NJ). The flooring system, sidewalks, and railings were added that year as were the concrete abutment caps. The girders themselves were in place in 1913. They date stylistically to ca. 1890, and they represent a rare remaining example of a 19th-century bridge type. Another lattice or open web deck girder bridge is located at Bergen Avenue (0900011), also built over the same line. The Ocean Ave. span is technologically and historically significant as a rare example of a once-frequent bridge type (Criterion C). Approximately six of the open-web deck girders, all thought to be wrought iron, have been identified in the state, and all but one are railroad related. Other examples are located in Warren, Hunterdon, and Middlesex counties. Only three still function as deck girders.

The bridge carries a four-lane city street over a mile-long double track cut built in 1869 for the Newark & New York RR, a subsidiary of the CNJ, through Bergen Hill, a long rock ridge separating the waterfront of Hudson County from the land to the west. The Newark & New York RR was built to give the shortest, fastest route between Newark and the CNJ ferry terminal at Communipaw. In the 1920s, 38 local passenger trains traversed this route each way every weekday, stopping at four stations in the single mile of this cut in Jersey City. Passenger service ended in 1948 and the line was single tracked and used for freight only (Trains, p. 52). When Conrail took over the NJ's property in 1976, the line became the West Side Avenue Branch, but was abandoned by the mid-1980s. Track has been removed, and the right-of-way is now overgrown.

SETTING / CONTEXT The bridge is adjacent to NR-listed 1904-12 Dickinson High School. It bridges the Bergen Archways, a deep railroad cut built through Jersey City by the Erie RR 1907 - 1910 but now abandoned. The south arch spans an old trolley grade, parallel to but not as deep as the railroad cut. Stairs go from deck level to trolley grade level, suggesting the bridge served as shelter for a trolley stop.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Erie RR Main Line Historic District, Eligible. Erie RR Bergen Archway / Bergen Hill Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/20/98, Comments 3/10/99 4/27/00.

SUMMARY The 2-span reinforced concrete arch bridge is historically noteworthy as an original component of the Bergen Archways. It is also associated with Jersey City's former trolley network. It retains its concrete balustrade plus an old iron railing, and it is well preserved. The reinforcing is in the Monier tradition. The span ranks as the most ambitious early concrete arch bridge in the county. The bridge is individually eligible for listing in the National Register of Historic Places and is also an element of the Erie RR's technologically significant Bergen Archway / Bergen Hill Tunnel Historic District under Criteria A and C.

"The New Four-Track Line of the Erie Railroad Through Bergen Hill, Jersey City" Engineering News Vol. 58, No. 8 February 21, 1907 pp. 204-205

Physical Description: The bridge consists of two spans of reinforced concrete arches. It retains its original concrete parapets topped by a tall iron picket fence, also apparently original. Field inspection revealed that the bridge's reinforcing is visible where concrete has spalled on the intrados. The pattern revealed suggests that the reinforcement consists of a grid of steel rods fairly close to the surface. This type of reinforcement is reminiscent of that of the early concrete pioneer Monier, and also of present day practice. It is much lighter and more efficient than the Melan system in vogue at the time. The bridge is in deteriorating but unaltered condition.

Historical and Technological Significance: The 1910 reinforced concrete bridge is a representative example of its type, but it is historically important as an original element of the Bergen Archways, the open cut with interspersed tunnels that traverses Bergen Hill (also known as the Palisades) in Jersey City. The Bergen Archways was built 1907-1910 as a solution to the problem of getting a large quantity of commuter passenger trains from several different rail lines west of Bergen Hill to the Erie Railroad's passenger terminal on the waterfront of the Hudson River east of the hill. The Archways was a major engineering work in which more rock was removed than in any other such project up to that time; it was 4400' long, 60' wide at the bottom, and 40' to 75' deep. The bridge is individually historically significant due to its construction technology and its association with both the Bergen Archways and the trolley line it also spanned, and it is significant as a contributing resource to the potential Bergen Archways Historic District (Criterion C).

The bridges for Baldwin and Palisade Avenues were built while temporary bridges carried their traffic over the partially excavated cut. It is possible the same form work was used for the bridges as was used for the tunnel linings, since the latter was meant to be reused after each section was completed. Originally it was expected that the Palisade Avenue bridge would be a plate girder span of 80 foot, while the Baldwin Avenue bridge would be either of steel or concrete. By 1908 it had been decided to use reinforced concrete for the Baldwin Avenue bridge but the Palisade Avenue bridge was still to be of steel. In the end the Palisade Avenue bridge was also built as a reinforced concrete arch. Evidently these were the pioneering concrete arches for the Erie RR, and mark this project as a transition between the two materials. The result was a four-track route with four tunnels under major streets and street intersections, but open for most of its route to allow smoke and fumes from locomotives to escape. The route drew its name from the dramatic effect created by the "bridges of living rock" left standing over the cut, an effect emphasized by the width of the tunnels and the sheerness of the walls of the cut (Erie Railroad Magazine, P. 15).

The Archways ceased to be used for passenger trains in 1956-57 with the transfer of all Erie RR passenger trains to the Lackawanna RR's Hoboken Terminal. It continued to be used for freight trains until the mid-1980s, but is now abandoned and has become overgrown with trees and brush.

The Bergen Archways was an innovative solution to the problem of inserting a railroad corridor to accommodate a high volume of passenger traffic into a built-up urban area and through a solid rock barrier. It has two pioneering reinforced concrete arch bridges and its four-track tunnels carrying streets over the cut are probably the largest "tunnel bridges" (a tunnel primarily dug to serve instead of a bridge) in the state. It was designed by the engineering department of the Erie RR, G.H. Burgess, Principal Assistant Engineer, A.L. Moorehead, Resident Engineer, and F.L. Stuart, Chief Engineer. Millard Construction Company of Philadelphia was the contractor. The bridge is one of six structures on the Archways route (0951165-0951170), and all have been evaluated as significant because of their historic and technical associations with the significant right-of-way.

Boundary Description and Justification: The tunnel is significant within the historic context of the ambitious railroad right-of-way

development. It is part of a right-of-way that has visual, historical, and technical cohesiveness. The setting of the right-of-way is also fairly well preserved. Thus the tunnel and the entire 4400'-long Bergen Archways right-of-way are evaluated as a district with this structure being an individually eligible and a contributing resource.

"The New Four-Track Line of the Erie Railroad Through Bergen Hill, Jersey City" Engineering News Vol. 58, No. 8 February 21, 1907 pp. 204-205

Physical Description: The bridge consists of one reinforced concrete arch. It retains its concrete balustrade topped by a tall metal picket railing. The design or pattern of the reinforcement is not known. Since it was built as part of the same project as 0951165, the Monier-type reinforcing system of a gird of reinforcing rods was probably used for this span as well. This type of reinforcement is reminiscent of that of Monier, and also of present day practice. The span appears to be unaltered.

Historical and Technological Significance: In addition to being a well-preserved example of a reinforced concrete arch bridge reinforcing system, the 1910 overpass is historically important as an original element of the Bergen Archways, the open cut with interspersed tunnels that traverses as the Palisades in Jersey City. The 1907-1910 as a solution to the problem of getting a large quantity of commuter passenger trains from several different rail lines west of Bergen Hill to the Erie RR's passenger terminal on the waterfront of the Hudson River east of the hill. The Archways was a major engineering work in which more rock was removed than in any other such project up to that time; it was 4400' long, 60' wide at the bottom, and 40' to 75' deep (Criterion C). It is evaluated as significant because it is a contributing resource to the potential Bergen Archways Historic District.

The bridges for Baldwin and Palisade Avenues were built while temporary bridges carried their traffic over the partially excavated cut. It is possible the same centering was used for the bridges as was used for the tunnel linings, since the latter was meant to be reused after each section was completed. Originally it was expected that the Palisade Avenue bridge would be a plate girder bridge of 80 foot span, while the Baldwin Avenue bridge would be either of steel or concrete (Railway Age, p. 834). Reinforced concrete bridges were not very common at the time this project was planned. By 1908 it had been decided to use reinforced concrete for the Baldwin Avenue Bridge but the Palisade Avenue Bridge was still to be of steel, In the end, the Palisade Avenue bridge was also built as a reinforced concrete arch. Evidently, then, these were the pioneering concrete arches for the Erie RR, and mark this project as a transition between the two materials.

The result was a four-track route with four tunnels under major streets and street intersections, but open for most of its route to allow smoke and fumes from locomotives to escape. The route drew its name from the dramatic effect created by the "bridges of living rock" left standing over the cut, an effect emphasized by the width of the tunnels and the sheerness of the walls of the cut (Erie Railroad Magazine, p. 15).

The Archways ceased to be used for passenger trains in 1956-57 with the transfer of all Erie RR passenger trains to the Lackawanna RR's Hoboken Terminal. It continued to be used for freight trains until the mid-1980s, but is now abandoned and has become overgrown with trees and brush.

The 1907-1910 Bergen Archways was an innovative solution to the problem of inserting a railroad corridor to accommodate a high volume of passenger traffic into a built-up urban area and through a solid rock barrier. It has two pioneering reinforced concrete arch bridges and its four-track tunnels carrying streets over the cut are probably the largest "tunnel bridges" (a tunnel primarily dug to serve instead of a bridge) in the state. It was designed by the engineering department of the Erie Railroad and built by Millard Construction Company of Philadelphia. Their are six structures on the route (0951165-0961170), and all are evaluated as contributing resources to the historic right-of-way.

Boundary Description and Justification: The tunnel is significant within the historic context of the ambitious railroad right-of-way development. It is part of a right-of-way that has visual, historical, and technical cohesiveness. The setting of the right-of-way is also fairly

CONSULT STATUS Individually Eligible. Erie RR Main Line Historic District, Eligible. Erie RR Bergen Archway / Bergen Hill Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/20/98, Comments 3/10/99 4/27/00.

SUMMARY The bridge, best described as a tunnel lining, consists of a concrete arch (reinforced only near its portals) supporting solid rock above. The unaltered tunnel is cut through Bergen Hill (the Palisades) and is part of the Bergen Archways rail line developed by the Erie RR in 1907-10. A tunnel was used at the site instead of a bridge to minimize disruption of the streets and buildings above. The bridge is individually eligible for listing in the National Register of Historic Places. In addition, it is a contributing element of the Erie Railroad Bergen Archways / Bergen Hill Tunnel Historic District under Criteria A and C.

INFOR MATION

Bibliography:

"Beginning of Erie's Terminal Improvements," Railway Age. Vol. 46, (28 Dec. 1906), pp. 831-834.

"Erie Terminal Improvements in Jersey City" The Railroad Gazette Vol. XLIV, No. 20, May 15, 1908 pp. 669-672
"The New Four-Track Line of the Erie Railroad Through Bergen Hill, Jersey City" Engineering News Vol. 58, No. 8 February 21, 1907 pp. 204-205

Physical Description: The structure consists of an unreinforced concrete-lined tunnel through solid (diabase) rock for 250', then 300' of additional tunnel constructed by the cut-and-cover method (west of the previous portion) lined with reinforced concrete and topped with fill. Both portals are tied back into the rest of the lining with steel reinforcement. It was originally intended to drive the whole tunnel by standard tunneling methods, but the rock above the westernmost 300 ft. of the tunnel was sufficiently shallow and weak that all of it had to be removed. Rather than making this section open cut the tunnel lining was constructed anyway, with steel reinforcement added, fill was added, and the surface was restored, with a retaining wall constructed over the portal. This was done to avoid the loss of rental income from the land above.

Historical and Technological Significance: The concrete-lined tunnel is an original element of the 1907-1910 Bergen Archways tunnel-cut, an impressive engineering work and a major urban transportation corridor. It was assigned and developed by the Erie Railroad. The tunnel-cut was an innovative solution to the problem of inserting a corridor to accommodate a high volume of passenger traffic into a built-up urban area and through a solid rock barrier. The driving and lining of the tunnel, unusually wide for railroad structure, was complicated by the wide span (sufficient for four tracks), the treacherous inclination of the rock strata, and the presence of the old tunnel running just north of the work. In addition, the Archways was a major engineering work in which more rock was removed than in any other such project up to that time; it was 4400' long, 60' wide at the bottom, and 40' to 75' deep (Criterion C). The structure is evaluated as a contributing resource to the potential Bergen Archways Historic District.

The result of the improvement program was a four-track route with four tunnels, all evaluated as contributing resources, under major streets and street intersections, but open for most of its route to allow smoke and fumes from locomotives to escape. The route drew its name from the dramatic effect created by the "bridges of living rock" left standing over the cut, an effect emphasized by the width of the tunnels and the sheerness of the walls of the cut" (Erie Railroad Magazine p. 15).

The Archways ceased to be used for passenger trains in 1956-57 with the transfer of all Erie RR passenger trains to the Lackawanna RR's Hoboken Terminal. It continued to be used for freight trains until the mid-1980s, but is was abandoned and has become overgrown with trees and brush.

The Bergen Archways was an innovative solution to the problem of inserting a railroad corridor to accommodate a high volume of passenger traffic into a built-up urban area and through a solid rock barrier. The historic route also includes two pioneering reinforced concrete arch bridges with the four-track tunnels carrying streets over the cut in what is probably the largest "tunnel bridges" (a tunnel primarily dug to serve as a substitute for a regular bridge) in the region. Six structures (four tunnels and two bridges) have been evaluated as contributing resources to the potentially eligible route (0951165-0951170).

Boundary Description and Justification: The tunnel is significant within the historic context of the ambitious railroad right-of-way development. It is part of a right-of-way that has visual, historical, and technical cohesiveness. The setting of the right-of-way is also fairly well preserved. Thus the tunnel and the entire 4400'-long Bergen Archways right-of-way are evaluated as a district with this structure being an individually eligible and a contributing resource.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/20/98, Comments 3/10/99 4/27/00.

SUMMARY The structure is historically significant as an original element of the Bergen Archways. It is essentially unaltered from its original appearance and consists of a concrete-lined tunnel through rock supporting the road high above. A tunnel rather than a bridge was used at the crossing to minimize disruption to the existing neighborhood. The 1907-10 railroad route is a combination of open cuts, tunnels, and bridges over the open cuts through Bergen Hill. The bridge is individually eligible for listing in the National Register of Historic Places. In addition, it is a contributing element of the Erie Railroad Bergen Archways/Bergen Hill Tunnel Historic District under Criteria A and C.

"The New Four-Track Line of the Erie Railroad Through Bergen Hill, Jersey City" Engineering News Vol. 58, No. 8 February 21, 1907 pp. 204-205

Physical Description: The structure consists of a 60'-long, 200'- wide tunnel lined with unreinforced concrete (except that the portal is tied back into the rest of the lining with steel reinforcement). The tunnel runs through solid rock (diabase). The tunnel and entire right-of-way are now abandoned.

Historical and Technological Significance: The concrete-lined tunnel, one of four on the line, is historically important as an original contributing element of the Bergen Archways, the open cut with interspersed tunnels and overpasses that traverses Bergen Hill (also known as the Palisades) in Jersey City. Designed by the engineering department of the Erie Railroad, the right-of-way was built 1907-1910 as a solution to the problem of getting a large quantity of commuter passenger trains from several different rail lines west of Bergen Hill to the Erie RR's passenger terminal on the waterfront of the Hudson River east of the hill. The Archways was a major engineering work in which more rock was removed than in any other such project up to that time. The Archways route is 4400' long, 60' wide at the bottom, and 40' to 75' deep. The driving and lining of the tunnel was complicated by the wide span (sufficient for four tracks), the treacherous inclination of the rock strata, and the presence of the old tunnel running just north of the 1907 work (Criterion C). The structure is evaluated as a contributing resource to the Bergen Archways Historic District.

The result of the improvement program was an open cut four-track route with four tunnels under major streets and street intersections. The open cut allowed smoke and fumes from locomotives to escape. The route drew its name from the dramatic effect created by the "bridges of living rock left standing over the cut, an effect emphasized by the width of the tunnels and the sheerness of the walls of the cut (Erie Railroad Magazine. p. 15). At this point the Archways route parallels the Erie Railroad's original 1858 route through Bergen Hill. By the 1890s that old route was not adequate to handle the traffic volume.

The Archways ceased to be used for passenger trains in 1956-57 with the transfer of all Erie RR passenger trains to the Lackawanna RR's Hoboken Terminal. It continued to be used for freight trains until the mid-1980s, but is now abandoned and has become overgrown with trees and brush.

The Bergen Archways was an innovative solution to the problem of inserting a railroad corridor to accommodate a high volume of passenger traffic into a built-up urban area and through a solid rock barrier. It has two pioneering reinforced concrete arch bridges and its four-track tunnels carrying streets over the cut are probably the largest "tunnel bridges" (a tunnel primarily dug to serve as a substitute for a regular bridge) in the state. Six structures (four tunnels and two concrete-arch overpasses) have been evaluated as contributing resources to the potentially eligible route (0951165-0951170).

Boundary Description and Justification: The tunnel is significant within the historic context of the ambitious railroad right-of-way development. It is part of a right-of-way that has visual, historical, and technical cohesiveness. The setting of the right-of-way is also fairly well preserved. Thus the tunnel and the entire 4400'-long Bergen Archways right-of-way are evaluated as a district with this structure being an individually eligible and a contributing resource.

SETTING / CONTEXT This structure carries the Bergen Archways route under a neighborhood of modern apartment houses above. The Archways tunnel-cut was built by the former Erie RR 1907-1910 to carry a new four-track passenger line through the higher sections of Jersey City to the waterfront. The railroad is now abandoned and the cut is overgrown with brush and trees.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Erie RR Main Line Historic District, Eligible. Erie RR Bergen Archway / Bergen Hill Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/20/98, Comments 3/10/99 4/27/00.

SUMMARY The structure is significant as an original element of the "Bergen Archways" corridor. It is essentially unaltered from its original appearance. It consists of a concrete lined tunnel through rock supporting buildings and streets above. A tunnel was chosen instead of a bridge to minimize disruption of the neighborhood above. The tunnel lining is part of the historically and technologically significant route developed by the Erie RR 1907-1910. The bridge is individually eligible for listing in the National Register of Historic Places. In addition, it is a contributing element of the Erie Railroad Bergen Archways/Bergen Hill Tunnel Historic District under Criteria A and C.

SETTING / CONTEXT The structure carries the Bergen Archways route under an arterial street. The Archways is a tunnel-cut built by the former Erie RR 1907-1910 to provide a new four-track passenger line through the higher portions of Jersey City to the waterfront. Surrounding the structure is a mid-20th century urban commercial area. The railroad is now abandoned and the cut is overgrown with brush and trees.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Erie RR Main Line Historic District, Eligible. Erie RR Bergen Archway / Bergen Hill Tunnel Historic District, Eligible. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95, Opinion 02/20/98, Comments 3/10/99 4/27/00.

SUMMARY The concrete-lined tunnel is significant as an original element of the Bergen Archways route. It retains its original appearance unaltered. It consists of a concrete-lined tunnel with concrete retaining wall with the boulevard above. It is one of four concrete lined tunnels the Erie RR built on the Bergen Archways route 1907-1910. The rail line is historically significant in its approach to solving a difficult crossing of Bergen Hill to get to Hudson River and New York City. The bridge is individually eligible for listing in the National Register of Historic Places. In addition, it is a contributing element of the Erie Railroad Bergen Archways/Bergen Hill Tunnel Historic District under Criteria A and C.

"The New Four-Track Line of the Erie Railroad Through Bergen Hill, Jersey City" Engineering News Vol. 58, No. 8 February 21, 1907 pp. 204-205

Physical Description: The structure consists of a 60'-long, 200'- wide tunnel lined with unreinforced concrete (except that the portal is tied back into the rest of the lining with steel reinforcement). The tunnel runs through solid rock (diabase). A concrete retaining wall above the west tunnel portal retains fill. The tunnel is immediately south of the Erie Railroad's original 1858 double-track tunnel which was not within the scope of this survey. The western portal of the 1858 tunnel is adjacent to the western portal of the 1907 tunnel.

Historical and Technological Significance: The concrete-lined tunnel, one of four on the line, is historically important as an original contributing element of the Bergen Archways, the open cut with interspersed tunnels and overpasses that traverses Bergen Hill (also known as the Palisades) in Jersey City. Designed by the engineering department of the Erie Railroad, the right-of-way was built 1907-1910 as a solution to the problem of getting a large quantity of commuter passenger trains from several different rail lines west of Bergen Hill to the Erie RR's passenger terminal on the waterfront of the Hudson River east of the hill. The Archways was a major engineering work in which more rock was removed than in any other such project up to that time. The Archways route is 4400' long, 60' wide at the bottom, and 40' to 75' deep. The driving and lining of the tunnel was complicated by the wide span (sufficient for four tracks), the treacherous inclination of the rock strata, and the presence of the old tunnel running just north of the 1907 work (Criterion C). The structure is evaluated as significant because it is a contributing resource to the Bergen Archways Historic District.

The result of the improvement program was an open cut four-track route with four tunnels under major streets and street intersections. The open cut allowed smoke and fumes from locomotives to escape. The route drew its name from the dramatic effect created by the "bridges of living rock left standing over the cut, an effect emphasized by the width of the tunnels and the sheerness of the walls of the cut (Erie Railroad Magazine. p. 15). At this point the Archways route parallels the Erie Railroad's original 1858 route through Bergen Hill. By the 1890s that old route was not adequate to handle the traffic volume.

The Archways ceased to be used for passenger trains in 1956-57 with the transfer of all Erie RR passenger trains to the Lackawanna RR's Hoboken Terminal. It continued to be used for freight trains until the mid-1980s, but is now abandoned and has become overgrown with trees and brush.

The Bergen Archways was an innovative solution to the problem of inserting a railroad corridor to accommodate a high volume of passenger traffic into a built-up urban area and through a solid rock barrier. It has two pioneering reinforced concrete arch bridges and its four-track tunnels carrying streets over the cut are probably the largest "tunnel bridges" (a tunnel primarily dug to serve as a substitute for a regular bridge) in the state. Six structures (four tunnels and two concrete-arch overpasses) have been evaluated as contributing resources to the potentially eligible route (0951165-0951170).

Boundary Description and Justification: The tunnel is significant within the historic context of the ambitious railroad right-of-way development. It is part of a right-of-way that has visual, historical, and technical cohesiveness. The setting of the right-of-way is also fairly well preserved. Thus the tunnel and the entire 4400'-long Bergen Archways right-of-way are evaluated as a district with this structure being an individually eligible and a contributing resource.

CONSTRUCTION DT 1928 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT **BUILDER**

SETTING / CONTEXT Pershing Road comes down the face of the cliffs of the Palisades and at the bottom turns 90 degrees toward the Hudson River to cross this bridge over rail lines, now Conrail but formerly West Shore RR. It forms the main approach to a former rail yard now being redeveloped with new buildings for mixed uses. With the cliff as a backdrop the bridge's setting is visually impressive, but it does not include historic structures.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The stringer bridge supported on 3-column concrete bents and concrete abutments with earlier stone wingwalls is representative of the most common pre-World War II bridge type in the state. Concrete jack arches are set between the stringer, making this a late use of jack arches, which are seldom seen after World War I. The metal picket railing is original and is a standard period design, but the concrete barriers are modern. Despite the jack arches, the bridge is not technologically noteworthy.

TOWNSHIP JERSEY CITY

TYPE THRU TRUSS **DESIGN** WARREN **MATERIAL** Steel

 # SPANS 2 **LENGTH** 183 ft **WIDTH** 17.8 ft

CONSTRUCTION DT 1906 **ALTERATION DT** Demolished **SOURCE** NJDOT

DESIGNER/PATENT CNJ RR OFFICE OF ENGINEER **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carried a city street over the multi tracked main line of the CNJ railroad. It is now closed, and the railroad is reduced to a Conrail freight branch. The span is located on the east edge of an undistinguished urban residential area of late-19th and early-20th century rowhouses, all remodeled. To the east is vacant land formerly used for railroad purposes, and a busy highway (NJ 440).

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span rivet-connected bridge is composed of a Warren thru truss and a Warren pony truss supported on a stone abutment on the south and a concrete abutment on the north. Neither span exhibits unusual design details, but they are good, unaltered examples of their type and are thus technologically distinguished. The bridge is one of three thru trusses built in the vicinity by the CNJ RR between 1901 and 1910. Similar bridges built for the CNJ are in Union County.

INFOR MATION

Bibliography:
Anderson, Elaine. The Central Railroad of New Jersey's First 100 Years. Center for Canal History and Technology. 1984.

Physical Description: The slightly skewed 2-span bridge is composed of one 5-panel rivet-connected Warren thru truss span and a Warren pony truss approach span. The pony truss is unusual in that the end posts are not inclined. The southern abutment is stone while the one on the northern end is concrete. A built-up steel bent supports the middle portion. The verticals and diagonals of the thru truss are composed of laced back-to-back angles while the inclined end posts and top chord are built-up box sections. The portal braces are lattice, and the lateral braces are laced. The cantilevered sidewalk on one side only is enclosed with the original lattice railing. The bridge is closed to all traffic, but it appears to be in unaltered condition. Its details are not distinctive and are typical of the early 20th century.

Historical and Technological Significance: The 1906 two-span bridge is a representative example of common bridge types; the Warren thru truss and the Warren pony truss. Neither span exhibits any distinctive construction details. They are both typical of the type and details used by the CNJ throughout both Hudson and Union counties.

Historically the bridge chronicles Hudson County's important position in the transportation history of the greater metropolitan area, as do the four other metal trusses bridges the line built that survive in the county (0900003(demolished), 0962152(demolished), 0962154, 0962155). The county is rich in major rail corridors because of its location opposite New York City. The Central Railroad of New Jersey was chartered in 1847, after which it developed its route from Elizabeth to Jersey City and west to the anthracite coal region of eastern Pennsylvania. The route to Jersey City was completed in 1864. The bridge carries a city street over the former CNJ main line to an industrial area containing primarily the CNJ's locomotive facilities, once said to be the largest in the U.S. The yard, begun in the 1860s, was developed on filled land to handle passenger as well as freight trains. All elements of that facility were destroyed in the creation of Liberty State Park. This is one of four thru truss bridges the CNJ built in the area between 1901 and 1910. 0962152 (demolished Communipaw Avenue bridge built in 1908) has been evaluated as significant. CNJ thru truss bridges of similar age, type, and design are also extant in Union County.

DESIGNER/PATENT CNJ RR OFFICE OF ENGINEER **BUILDER**

SETTING / CONTEXT The bridge carries the former CNJ RR multi-track main line, now reduced to a single track Conrail industrial branch, over a city street. It is located in an undistinguished urban residential and commercial area, with a modern plumbing supply house and yard to the northwest. The neighborhood also contains modernized row houses of indeterminate age, and post-1950 brick houses and small apartment buildings.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-span thru girder bridge with built-up steel bents is composed of six girders, formerly carrying five tracks. The center four spans have the thru girder for only the main span with stringers for the approaches while the outermost spans are same-depth thru girders for all three spans. The abutments and wingwalls are concrete. The bridge is essentially identical to 0963154, and it is a relatively early but not technologically or historically distinguished example of its common type.

DESIGNER/PATENT UNKNOWN **BUILDER** WPA CREW (?)

SETTING / CONTEXT The bridge carries a two-lane county road over a minor stream in a wooded suburban area on what was the main road into Flemington. The heaviest traffic now bypasses this road. The adjacent 18th-century farm and outbuildings and Greek Revival house are well maintained with spacious grounds. The bridge is included within the physical boundary of the National Register-listed Flemington Historic District, but it is was built after the district's period of significance.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Flemington Historic District. 09/17/1980. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The encased stringer bridge presents the facade of an elliptical stone arch. Low stone recessed mortar parapets end in stone end posts supporting cast iron lamp standards. Planters are recessed in both parapets. A plaque identifies the span as an WPA Work Project. Ornate design elements and entrance location link the span to the City Beautiful movement. Although built after the district achieved its significance, the well-preserved bridge is an eligible resource in its own right.

INFOR MATION

Bibliography:
Seely, Bruce. Building the American Highway System. 1987. Hunterdon County Engineer. Bridge File: Q-19.

Physical Description: The 29'-long encased stringer bridge on a concrete substructure is finished to appear as an arch. The rubble-coursed stone spandrel wall presents an arched waterway opening. The flared wingwalls, parapets, and end posts are similarly detailed, and planters are set into the tops of the parapets. The original cast iron light standards are still in place atop the end posts, but the luminaries are not. The bridge is well preserved.

Historical and Technological Significance: The 1934 encased stringer bridge is historically significant as an example of the City Beautiful philosophy and the product of Depression-era work relief projects that were used effectively to upgrade the nation's infrastructure in the 1930s (criterion A). The bridge is finished in the rustic mode, making it the most ambitiously detailed, county-built stringer span in Hunterdon County. It is located on what was the highway into Flemington, the county seat, which accounts for its custom detailing. it was designed to serve as a proper entryway into the community.

According to county records, the span was constructed as a federally funded Emergency Relief Administration project. Such projects were developed by the Roosevelt administration as a means of making work during the depths of the Depression. With the drop in local funds due to a marked decline in property taxes collected, the federal money allocated to counties made road and bridge work possible in New Jersey and every other state in the Union during the 1930s. The influx of federal money, administered through the Bureau of Public Roads, made it possible to continue the "golden age of highway construction" through the Depression. Such projects were accomplished with some federally mandated requirements to increase employment, like hand work as opposed to power equipment, and custom detailing, like stonework, that was labor intensive. This bridge ranks as one of the most distinctive examples of Depression-era federally-funded bridge projects in the state.

Boundary Description and Justification: The bridge is located within the boundary of the National Register-listed Flemington Historic District, but it was built after the 18th- and 19th-century period of significance of the district. It therefore is a noncontributing resource to the historic district. The bridge is evaluated as distinguished in its own right. Thus the bridge and its setting are significant. For a precise definition of the boundary of the historic district, refer to the National Register file at NJHPO.

CONSTRUCTION DT 1927 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT GRANT DAVIS, CO ENG **BUILDER** SNOOK BROTHERS

SETTING / CONTEXT The two-lane bridge carries County Route 614 over a tributary of Hakihohake Creek. It is located in a wooded rural setting near open fields and sparse housing. A 19th-century farmstead is adjacent to the bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete encased steel stringer bridge is supported on concrete abutments with wing walls. It has paneled concrete parapets. Concrete buttressing has been added to the original abutments. One of over 75 stringer bridges in the county, it was a design commonly employed by the county and state in post-WW I road improvement projects. It is not technologically or historically noteworthy.

DESIGNER/PATENT FRANK W. BOHREN, CO ENG **BUILDER** WM SCHAAF

SETTING / CONTEXT The bridge carries a 2-lane county road with shoulders over a minor stream. It carries moderate traffic and is located in a rural setting near the edge of Frenchtown. There is a scattering of mixed commercial and residential buildings. An oil storage facility is located next to the bridge.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete rigid frame bridge has concrete wingwalls and standard design concrete balustrades. The fascia of the span has a slight arch form. A plaque identifies the span as the first of its type in the county, and it is the only one built by the county that remains. However, the form was in use in New York beginning in 1920, and was common by the 1930s. Although the type is unusual for the county, the technology is not innovative.

DESIGNER/PATENT UNKNOWN **BUILDER** COUNTY FORCES

SETTING / CONTEXT The bridge carries 2 lanes, shoulders, and sidewalks over a minor stream in the architecturally and historically significant 19th-century town of Lambertville. It is located at a crossroads. The historic traffic pattern in the town was altered this century when the NJ 29 bypass was built. South Franklin Street is now only a few blocks long. The bridge is located in the Lambertville Historic District. It is one of three 1870s stone arch spans in the district (100Y040, 100Y041).

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Lambertville Historic District. 06/30/1983. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The graceful elliptical stone arch bridge has undergone few alterations. Concrete parapets have been added. The arch opening is defined by ringstones. A stone post in the center of the later concrete balustrade is inscribed. The roadway has granite curbstones and Belgian pavers. The bridge was built within the period of significance of the Lambertville Historic District, and its historical role in the transportation system of the village makes the bridge a contributing resource.

INFOR MATION

BIBLIOGRAPHY:

Hunterdon County Engineer's Office, Bridge Card Y1.
Hunterdon County Cultural and Heritage Commission: The First 275 Years of Hunterdon County, 1714-1989. Flemington, New Jersey, 1989.

PHYSICAL DESCRIPTION: The elliptical stone arch bridge was built in 1872, as inscribed in a commemorative stone post that also bears the names of the three committee members, S. Lilly, J. Bird, and S.B. Bray. The 40'-long arch that is finished with gauged rusticated ringstones is constructed of the locally common gray granite stone which was quarried at nearby Raven Rock. In contrast to the regular coursed ringstone are the rubble-coursed spandrel walls. Stone end posts and center post on either side of the bridge are embedded in newer reinforced concrete parapets that are unadorned. The bridge is a 24 feet wide with two sidewalks with granite curbstones and Belgian pavers which have been covered with macadam. Long stone wingwalls have been repointed as have the spandrel walls. No other alterations are apparent.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The 1872 stone arch bridge is located in the National Register-listed Lambertville Historic District, recognized for its transportation and architectural significance. Lambertville is a town which was shaped by transportation systems. Located on the Old York Road from Philadelphia to New York, its growth surged with the opening of the D&R Canal Feeder in the early 1830s. The Feeder, an important link with industrial Trenton and Philadelphia with the rich eastern Pennsylvania coal fields, carried its peak loads in the 1860s. In addition to the canal feeder, which was open to marine traffic until about 1913, Lambertville was also the site of the main shops of the Belvidere & Delaware Railroad, built by the Camden & Amboy Railroad from Trenton to Warren County and opened in 1851. The railroad played a significant role in the late-19th and early-20th century growth of the community as did roads linking surrounding communities. This bridge is situated on the old Ringoes-Trenton road at its crossroads with the Hopewell Road. Technologically the stone arch is representative of what by 1872 was common technology. It is significant because it was built within the period of significance of the historic district and that it contributes to the historic character of the district. It is one of three stone arch bridges in the historic district. All are evaluated as contributing resources because of their dates of construction and state of preservation

SETTING / CONTEXT The bridge carries a quiet 2-lane with sidewalks residential street over Swan Creek in Lambertville. It is surrounded by 19th-century homes and retail businesses. The bridge is one of six over Swan Creek in the Lambertville Historic District which encompasses most of the city. The district recognizes the 19th-century architectural and transportation significance of the community. A utility pipe has been added through the arch.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Historic District Status Unresolved. Listed. Lambertville Historic District. 06/30/1983. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete deck arch bridge is finished with a concrete balustrade with vase-shaped balusters and paneled posts. Many of the balusters have been replaced with plain ones. Although the bridge perpetuates the local preference for arch spans, it is not a technologically distinguished example. It is altered, and it is outside the 19th-century period of significance of the National Register-listed Lambertville Historic District. It is thus a noncontributing resource.

 # SPANS 2 **LENGTH** 30 ft **WIDTH** 25.7 ft

CONSTRUCTION DT 1921 **ALTERATION DT** **SOURCE** NJDOT

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries a lightly traveled 2-lane county road over a minor stream in a suburban setting on the edge of the borough of Lebanon. Modern housing and commercial development are nearby.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span slab bridge is supported on rubble stone abutments and a concrete pier. Fieldstone wingwalls are capped with concrete. The bridge has been widened in kind. The downstream side of the stone abutments has been extended with concrete. Modern guide railings delineate the edge of the bridge. It is a well-represented example of a common bridge type is not technologically or historically distinguished.

SETTING / CONTEXT The bridge carries one lane of an unimproved rural road over a minor stream in a wooded hilly setting.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The rubble-coursed stone arch bridge is founded on bedrock on one side. It has voussoirs, but no keystone, and a recessed spandrel wall. The stone parapet is nearly level with the raised roadway. An inset plaque identifies the bridge as Cold Water Bridge. Although the parapet has been repaired, this example of traditional stone arch technology appears to be relatively unaltered, and it is historically significant as the oldest documented bridge in the county.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Master Plan: Sites of Historic Interest. 1979.
Hunterdon County Engineer's Office. Bridge File D329.

PHYSICAL DESCRIPTION: The 23'-long and nearly 13'-wide barrel fieldstone arch bridge with a high rise was constructed in 1849, according to an inscribed plaque inset on the upstream outside parapet wall. The decorative plaque also is inscribed with the initials "J.S.+ W.S., W.E., N.M.+C.M." and "Mason, P. Dyck." The bridge appears to be well preserved . Some re-pointing is evident at the footing and parapet. Most of the mortar on the intrados has fallen out. The span offers no physical evidence to indicate that bridge was widened. The roadway has been raised, making it nearly level with the 3'-high parapets.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The bridge is historically significant as one of the oldest and best preserved stone arch bridges in the county. A representative example of a bridge technology that dates to earliest history of this county, the span is not technologically innovative, but it does serve as a noteworthy local record of the oldest type of bridge technology in Hunterdon County. In addition to its historical significance, the bridge enjoys integrity of setting, being located on a quiet rural road in a cluster of 19th-century houses.

Boundary Description and Justification: The bridge is evaluated as individually significant. Thus, the boundary is limited to the span itself, including back walls and wing walls.

SUMMARY The concrete encased steel stringer bridge is supported on random ashlar abutments reinforced with concrete and a concrete pier. A combination of period pipe railing and modern metal guide railing delineates the bridge. The bridge is a representative example of a common bridge type and is one of over 75 stringer spans in the county. It is not technologically or historically significant.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The traditionally composed pin-connected Pratt half hip pony truss bridge is supported on one stone and one concrete abutment. Alterations have compromised the design integrity of the bridge. Numerous welded additions and repairs include gusset plates at the panel points, additional diagonals, plates at the end posts, outriggers and guide railings. One of over 20 Pratt half hip pony truss bridges in the county, other documented examples with greater integrity and significance exist (10XXB26).

DESIGNER/PATENT NJ STATE HWY DEPT BRIDGE DIV **BUILDER**

SETTING / CONTEXT The bridge carries busy four lane US Route 22 over one line of the Central Railroad of New Jersey. It was originally built to cross two lines of track. It is located in a rural setting of open fields and sparse housing.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Central Railroad of NJ Main Line Corridor. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95. DOE 11/30/95.

SUMMARY The skewed three span encased steel stringer bridge is supported on concrete abutments with wingwalls and column bents with crash walls. It has concrete balustrades on either side. It is an undistinguished example of the design commonly used by the county and state for both highway and railroad overpasses prior to World War II. Although well-preserved, it is not technologically or historically noteworthy.

SETTING / CONTEXT The bridge carries one lane of a quiet country road over a minor stream in a wooded setting with sparse housing. It is at the crossroads of three lightly traveled country roads. The setting is unspoiled.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-panel pony truss bridge is a hybrid modified Warren design with predominantly riveted connections. The reinforced floorbeam is suspended from a pin at the lower panel points. A non-functioning vertical rod extends from the pin and is secured to the top chord by a ball finial. The original lattice railings remain. It's similar to nearby 100D390. Despite 1970s minor alterations, the original design is preserved. It is historically significant as the work of a local fabricator and its design.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office, Bridge card D388.
Schmidt, Hubert G. Rural Hunterdon: An Agricultural History. New Brunswick: Rutgers University Press, 1945.

PHYSICAL DESCRIPTION: The two-panel, pin-connected slightly skewed Warren pony truss bridge has several unusual features. The top chord is a riveted box member consisting of angles and plate and a continuous cover plate, bent at the inclined end posts. Gusset plates secure the diagonals at the lower panel points. The bottom chord and diagonals are toe-in angles. The vertical member, a modification to the original design made after 1974, consists of two angles with a center separating batten and a central rod which threads through the top chord into a fastening finial. The bottom of the rod is a forged loop that passes around the pin that U hanger for the single flame-cut floor beam. The bridge is supported on random fieldstone abutments with wingwalls. The original medallion and lattice railing remains, but collision damage has buckled the east end post and railing. Concrete scour protection has been added, and a concrete toe wall has been added to the east abutment. Other minor repairs include welded reinforcing plates at the bottom of one inclined end post.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The diminutive pony truss bridge is technologically distinguished because it is a hybrid design variation on a Warren truss that reflects the experimental nature of metal truss bridge design in the 19th century. One of two nearly identical spans built over Plum Brook between 1900 and 1903, the designer is not documented, but it is probable that it was the builder of both spans, J. W. Scott, a fabricator from Flemington. According to Hubert Schmidt, Scott operated a foundry which specialized in the manufacture of iron bridges "during the latter part of the nineteenth century." (Schmidt, 220.) Scott also built two thru-truss bridges at Woodfern in Somerset County (18B0511, 18B0512). Like its companion (100D390), the bridge has minor alterations and repairs, but its design integrity and setting have not been compromised. The two bridges are the only documented examples of their design in the state, and while not representing the state of engineering or understanding of sound engineering principles of their day, do represent the variety and idiosyncrasy of bridge designs that characterize the heyday of the metal truss bridge era. Because both bridges are relatively well preserved, both have been evaluated as significant.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is thus limited to the bridge itself and includes the superstructure and substructure.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed 2-panel pony truss bridge supported on stone abutments is a hybrid design based on a Warren truss. The floorbeam is suspended by a U-bolt and pin at the panel point. A vertical rod extends between the pin and the top chord where it is held by a ball finial. There are welded strengthening ca. 1960, but the bridge is of unusual design, and it was built by a local fabricator. It is one of two nearly identical spans (100D388), and it is historically and technologically significant.

INFORMATION

Bibliography:
Hunterdon County Engineer. Bridge File: D39.
Schmidt, Hubert. Rural Hunterdon: An Agricultural History. 1945.

Physical Description: The 30'-long, one-span hybrid pony truss bridge is a modified Warren truss that incorporates design elements that are not well founded in standard engineering practice. The top chord and inclined end posts of the two-panel bridge is a riveted box member consisting of toe-in angles with riveted cover plate. An additional cover plate has been welded to the original cover plate on the top chord. The interior diagonals and bottom chord consist of a pair of angles with battens. All connections are riveted gusset plates. The only floor beam is hung by a U bolt that passes over a pin at the interior panel point. The floor beam is totally supported by the bottom chord, but the design includes a curious arrangement of a non-functional loop-forged eye rod that extends from the pin to the top chord, where the rod is anchored by a ball final. The member does not provide the usual bracing of the top chord. Welded outrigger has been added since 1974 to the center panel point to provide lateral bracing. The bearings are sliding plates, and the abutments are rubble-coursed fieldstone.

Historical and Technological Significance: The diminutive hybrid variation of a Warren pony truss bridge is unusual in its design with a non-functional eye bar connecting the lower panel pin floor beam hanger pin with the top. One of two nearly identical spans built for the county between 1900 and 1903 by local designer and fabricator J.W. Scott of Flemington, it is significant as an example of the variety of idiosyncratic designs generated by the late-19th century desire to produce strong but economical metal truss bridges during the last quarter of the 19th century and the first decade of the 20th. This and its nearby companion (100D390 that is also evaluated as significant) over the same feature in the same township are the only documented example of this variation on a Warren truss in the state.

The span was designed and built by James W. Scott, a Scot who operated a foundry which specialized in the manufacture of iron bridges "during the latter part of the nineteenth century" (Schmidt, p. 220). Scott also built bridges in Somerset County with the two-span pin-connected Pratt thru truss at Woodfern Road in Branchburg Township in Somerset County (18B0511, 18B0512) being one of the largest. It is known that Scott bid many jobs in both Hunterdon and Somerset counties. Historically he and his small operation represent how bridges were built in the era before the rise of the professional county engineer. Fabricators, like Scott, not only submitted both designs as well as actual construction bids to the bridge committee of the Board of Chosen Freeholders, who spent a large percentage of the time dealing with the construction of bridges on local roads. A fabricator often submitted more than one bid for each bridge, as the county-generated request for bids did not specify a bridge type prior to the hiring of the county engineer who designed and spec'ed bridges rather than relying on the fabricators to do so.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The boundary is thus limited to the substructure and superstructure of the span itself.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-panel riveted Warren pony truss bridge is supported on ashlar abutments which have been widened with concrete. One wingwall is stone, the others are concrete. When the bridge was widened in 1947, the entire flooring system was redone. The top chord of back-to-back angles has an added welded cover plate, and welded reinforcing has been added to upper panel points. Design integrity has been compromised. The undocumented, altered span is one of more than 20 similar bridges in the county.

DESIGNER/PATENT WROUGHT IRON BRIDGE CO. **BUILDER** WROUGHT IRON BRIDGE CO.

SETTING / CONTEXT The bridge carries one lane of a quiet country road over a minor stream in a wooded rural setting, near an 18th-century mill converted to a house. The surrounding area is residential with scattered houses dating from the 18th through the 20th centuries.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed 3-panel Pratt half hip pony truss bridge is pin-connected with cast iron connectors. The west abutment is stone encased in concrete. The east abutment and wingwalls were rebuilt in concrete in 1955. The bottom chord is stamped eye bars with shop numbers. Many welded alterations, including plates on the top chord and the cast connections, additional diagonals, and outriggers. The cast details are found on better preserved bridges in the county. This altered span is not distinguished.

SETTING / CONTEXT The bridge carries a 2-lane county road over a tributary of Back Brook. It is located in a wooded rural setting on a moderately traveled road. The land is used for agriculture.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The totally welded 4-panel Warren with verticals pony truss bridge was constructed in 1937. It is supported on abutments that are random ashlar on the downstream side and concrete on the upstream side. Wingwalls are stone. All members are either H or I sections. The bridge is the earliest remaining all welded construction bridge in the county. The technology, which is still being used for truss bridges, was utilized by the railroads as early as 1928. The structure is the largest of all the welded truss bridges and has exceptionally deep floor beams. The structure does not convey the historic period and the rural context where welded truss bridges traditionally were built has been compromised. This structure is not individually eligible for listing in the National Register of Historic Places and does not contribute to an historic district.

SETTING / CONTEXT The bridge carries one lane of a quiet country road over a minor stream in a wooded rural setting, adjacent to a plant nursery.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel Warren with verticals pony truss of riveted construction bears on concrete abutments with stone wingwalls. The use of heavy box sections in the design is an example of a secondary stress design. Floorbeams are riveted to angles which are riveted to the gusset plates at the lower panel points. The pipe railings are original. There are some welded repairs. The bridge is a noteworthy example of the work of local fabricator The Dover Boiler Works that was active until at least 1919.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office, Bridge Card E239.
Hunterdon County Master Plan: Sites of Historic Interest. 1979.

PHYSICAL DESCRIPTION: The four panel, 65'-long, Warren with verticals pony truss bridge of riveted construction is supported on concrete abutments. The top chord and inclined end posts are built-up box members composed of channels, toe in, with riveted cover plate on the top and lacing on the underside. Verticals are composed of angles with lacing as are the interior diagonals. The bottom chord is plate riveted at the panel points to square gusset plates. The floor beams are attached to the panel points by riveted angle hangers. The pipe railing on the bridge and one approach is original. The bridge has a concrete deck. Modifications to the original design are minimal, limited primarily to small welded repairs and concrete reinforcement.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: In addition to being technologically distinguished as a notable representative example of a riveted Warren pony truss bridge, the 1914 span is historically significant as a well-preserved example of the work of The Dover Boiler Works. The Dover, New Jersey firm is documented as having begun fabrication of bridges in 1901 (Darnell, 32), and they continued building truss bridges in Hunterdon, Somerset, and Morris counties through at least 1919.

The riveted Warren pony truss was one of the most common bridge types in this country during the last decade of the 19th and first three decades of the 20th centuries. The Warren pony truss bridge is well represented in Hunterdon county where 25 dating from the 20th century survive. This example was evaluated as a significant representative example because of its state of preservation, integrity of setting, and historical association with a local fabricator.

Boundary Description and Justification: The span is located on an unspoiled country road. It is individually distinguished, so the significant boundary is limited to the span itself.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 5-panel Warren with verticals pony truss uses riveted construction. It is supported on concrete abutments with wingwalls. It was installed at this site in 1957, replacing an 1830 2-span stone arch bridge, and it appears that it is an earlier truss rebuilt for this location. The original date of the trusses is not documented, but stylistically it is a ca. 1920 span. The bridge is a representative example of a common type and is not technologically or historically distinguished.

DESIGNER/PATENT I. P. BARTLEY & CO. **BUILDER** I. P. BARTLEY & CO. (1887)

SETTING / CONTEXT The bridge carries 2-lane wide Main Street over the South Branch of the Raritan River. It is located in the Califon Historic District, surrounded by 19th century residences and shops. Described in the nomination as "a documentary of life in a small 19th century rural based village," Califon was a stop on the High Bridge Railroad. The bridge was part of the farmers' access to market.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Califon Historic District. 10/14/1976. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY In order to retain the 1887 full hip, pin connected Pratt thru truss bridge, it was widened and converted to a stringer span in 1985. The ashlar abutments were extended with concrete. The original lateral, sway, and portal braces were spliced with in kind material to accommodate the widening. The original plaque, cresting, and ball finials remain. Although it has been widened, the trusses themselves are well preserved. As a result, the structure retains Its individual eligibility for listing in the National Register of Historic Places under Criteria A and C, and remains a contributing element of the Califon Historic District.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office Bridge card J1.
Hunterdon County Master Plan: Sites of Historic Interest. 1979.
NJHPO. National Register Files: Hunterdon County; Califon; Califon Historic District.

PHYSICAL DESCRIPTION: The single-span pin-connected thru truss bridge with cantilevered sidewalks was rehabilitated and widened in 1985, when it was converted into a stringer span with a thru-truss superstructure. Prior to 1985 the floor beam hangers and diagonals in the outside panels had been strengthened. The sensitive rehabilitation considered aesthetic elements, duplicating lattice portals and retaining original fabric. Decorative finials, balls, and plaque remain. The plaque identifies the builder as I. P. Bartley of Bartley, N.J. The original pin connections and elongated hangers are still present. The original fieldstone abutments are encased in concrete. Some original steel fabric is stamped "Carnegie."

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The pin-connected Pratt thru truss bridge built in 1887 is individually historically significant as an example of a small local bridge-building firm, I.P. Bartley of Mount Olive Township in nearby Morris County. The bridge is one of less than 5 examples of the firms work. It was widened in 1985 when rolled I-section steel stringers were added beneath the trusses and the bridge functionally became Although the bridge is located within the a stringer rather than a truss span, but the original fabric of the span was preserved.

In addition to its historic significance, the bridge is located in the National Register-listed Califon Historic District. It was not rated in the nomination, but it was built within the period of significance of the district, and it contributes to the historic theme or area of significance of the district. The nomination describes the district as presenting "a documentary of life in a small nineteenth to twentieth century rural-based village in the Musconetcong Valley..." as it existed between the years of 1870 to 1920. The bridge allowed the surrounding farmers access to the mills and railroad station of the village of Califon, and it was thus an important element in the historic development of the village.

Although the bridge has been altered, the alterations were accomplished in a sensitive and non-obtrusive manner. The picturesque bridge contributes to the character of the late Victorian-era street scape. It was a key element in the development of the village as a trading and shipping point. All of these factors argue for inclusion of the structure as a contributing resource to the historic district.

Boundary Description and Justification: The bridge is a contributing resource in an National Register-listed historic district. The bridge and its setting are significant. For a precise delineation of the Califon Historic District boundary, refer to the National Register file at NJHPO.

SETTING / CONTEXT The bridge carries one lane of a lightly travelled rural road over the scenic Musconetcong River, the boundary between Hunterdon and Warren counties. The bridge is located in a wooded rural area.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 5-panel pin-connected half hip Pratt pony truss is supported on stone abutments and concrete backwalls. It exhibits no distinctive design details. The eye bars are stamped. The span is a late example of a common bridge type in the county. While technically undistinguished, it is one of the few documented examples of the Smith Bridge Company of Toledo, a small firm established in 1890. The historical interest is augmented by the fact that the span is well preserved.

INFOR MATION

Bibliography:
Hunterdon County Engineer's Office. Bridge File:L-25W.
Darnell, Victor. Directory of American Bridge Building Companies 1840-1900. SIA, 1984.

Physical Description: The 5-panel, pin-connected Pratt half hip pony truss bridge supported on ashlar abutments is 70' long and 15' wide. It is composed of steel sections with the top chord and inclined end post of channels with cover plate and the verticals of channels joined by battens. The eyebars used for the lower chords and diagonals are stamped while the counters are round bars with forged eyes. The rolled I-section floor beams are hung from the panel points on U-shaped suspenders. the roadway deck is wood. alterations appear to be limited to the addition of welded outriggers and a protective rail welded to the inside face of the truss lines.

Historical and Technological Significance: Although a late example of a pin-connected Pratt pony truss bridge, the most common bridge type from the last two decades of the 19th century, the 1905 Point Mountain Road bridge is historically significant because it is the product of a small Ohio bridge fabricator, the Smith Bridge Company of Toledo. Robert W. Smith moved his wood truss bridge works established in 1867 from Tippicanoe City (Ohio) to Toledo in 1869. There he built composite (wood and metal) trusses, and in 1870 he formed Smith Bridge Company which he sold in 1890. The new owners changed the name to Toledo Bridge Company and later sold to American Bridge Company in 1901. Smith, however, went back into business as Smith Bridge Company. How much past 1905 the small operation continued is not known, but this span is one of the few documented examples of their activity in New Jersey.

Smith Bridge Company is historically significant in that its history represents how metal truss bridges were manufactured and marketed during the last quarter of the 19th century. Using standard shapes and fairly standard designs, small companies like Smith Bridge Company fabricated trusses that were marketed to county officials through regional agents. The historical significance of the span is enhanced by the fact that it survives in such a complete state of preservation, and the historical and technological value of the structure combine to make it a significant example of its genre (criterion A). Ohio was a particularly fertile state for bridge fabricating companies which was the home state for giants like Canton's Wrought Iron Bridge Company and smaller concerns like the Massillon Bridge Company and the Champion Bridge Company of Wilmington.

Many of these smaller companies, like Wrought Iron Bridge Company and Toledo Bridge Company, the group that bought Smith's first company in 1890, were amalgamated into J.P. Morgan's and then United States Steel Corporation's American Bridge Company starting in 1900. Although that the American Bridge Company consolidation then controlled 50% of the nation's fabricating capacity (Darnell, p. 85), small concerns like Smith Bridge Company did continue to be successful through the 1900s. The change in technology with the widespread acceptance of the rolled stringer span was the reason most companies like Smith's abandoned their bridge fabricating operations in the 1910s and 1920s (refer to corporate histories of Dover Boiler Works and Berlin Construction Company).

Boundary Description and Justification: Located in an unspoiled wooded setting on a lightly traveled road, the bridge is evaluated as individually significant. Although the setting is pleasant, it does not possess National Register significance. The boundary is thus limited to the superstructure and substructure of the span itself.

SETTING / CONTEXT The bridge carries one lane of a lightly traveled road over a minor stream. It is located in a wooded village setting, adjacent to modified 19th- and 20th-century homes, barns, and a converted mill and race downstream from the bridge. The village does not have historic district potential because of alterations and intrusions.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-panel pin-connected queen post pony truss bridge is supported on random ashlar abutments with wingwalls. Rod stock is used for all members except the top chords and end posts, which are built-up. Loop forged eye bar members are joined at the lower panel point by a single pin which also holds the floor beam U hanger. The well preserved, hybrid span is technologically distinguished, and it is also a contributing element to a potential historic district.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Master Plan: Sites of Historic Interest, 1979.
Hunterdon County Cultural & Heritage Commission. The First 275 Years of Hunterdon County, 1714-1989. Flemington, New Jersey, 1989.

PHYSICAL DESCRIPTION: The 46'-long bridge is a single span wrought iron pin-connected queen post pony truss span supported on an ashlar substructure. The truss consists of built-up portals and top chord of channels with a top cover plate and battens. The rivets are small and widely spaced. Other members are composed of bar stock with loop-forged eyes at both ends, which is used for the verticals as well as the bottom chords, diagonals, and counters with sleeve nuts for adjustments. The vertical eye bars are more widely spaced at the lower pin connection as they are set outside the eye bars for the diagonals and lower chord. The expansion bearing is a sliding plate on a cast iron masonry, or bearing, plate. The original pipe railings on the bridge and two of the approach wingwalls are original as are the loop-forged brackets that affix them to the trusses. Alterations are minimal. Outriggers have been welded to the top chords and floor beams, and some welding has been done at the bearings.

HISTORICAL AND HISTORICAL SIGNIFICANCE: The 3-panel queen post pony truss bridge is technologically significant as a rare and well-preserved example of its type. It is also noteworthy for its construction details with loop-forged eye bars used for the verticals. The span appears to be of wrought iron, and while not documented in the records of the Hunterdon County engineer, stylistically the span dates to ca. 1890. The bridge is well preserved, and it ranks as one of the several idiosyncratic pony truss spans in the county. It is important in documenting the evolution of metal truss bridge design, which as late as 1890 was still an era of experimentation in both design and material use.

In addition to its technological significance, the bridge is a contributing resource in a potential historic district. It is located on the northeastern edge of the borough of Milford, a well-preserved 19th-century settlement. Milford, once known as "Burnt Mills," was, by 1880, a center for lumber and agricultural trade on the Delaware River. It boasted three churches, four stores, two hotels, two gristmills (one of which is within site of the bridge), a sawmill, a drug store, a hardware store, a carriage shop, two blacksmiths, a post office and a railroad depot serviced by the Belvidere & Delaware Railroad. Despite some late-20th century development, Milford retains its 19th century character, and the Mill Street bridge dates from its period of significance, which extends through World War I.

Boundary Description and Justification: The bridge is individually distinguished, but it is also located on the northeast edge of the potential historic district of Milford village. Thus the bridge and its surroundings are significant.

SETTING / CONTEXT The bridge carries a 2-lane county road over a minor stream. It is located on the edge of the town of Frenchtown, in a wooded setting of sparse housing. The road carries moderately heavy traffic. Old stone abutments from an earlier, non-extant span are just downstream from this structure.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The reinforced concrete deck arch bridge has been extensively altered. The original arch has been encased in new concrete in a recent widening project. Modern guide railing delineates the edge of the bridge. The arch bridge is one of over ten bridges of this type in the county. The form is better represented by the arch bridges located in Lambertville. This span is not technologically or historically significant.

SETTING / CONTEXT The bridge carries one lane of a country road over a stream. It is located in a wooded setting surrounded by fields and meadows and a handsome 18th-century house that has been reworked in the Colonial Revival mode. A 1757 mill site (non-extant) is nearby. The picturesque, unspoiled setting contributes to the historic character of the bridge. The bridge has integrity of setting.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The two-span riveted Pratt half hip pony truss bridge is supported on a fieldstone substructure. Each 3-panel span is composed primarily of back-to-back angles with web gussets, which is not an uncommon style. Square-headed bolts hold the floorbeams to the gusset plates. Original pipe railings remain. Minimal changes include concrete toe walls and welded outriggers. The bridge is undocumented, but it one of the few riveted Pratt half hips and is thus a good example of its type.

INFOR MATION

Bibliography:
Hunterdon County Engineer. Bridge File: R 24

Physical Description: The 2-span riveted Pratt half hip bridge is supported on a rubble-coursed fieldstone substructure to which some concrete toe walls have been added. Each approximately 35'-long span is three panels, and the members are composed of angle set back-to-back with the gusset plates at all panel points set between the angles. The detail is not uncommon, and it is a design frequently found on Dover Boiler Works bridges. The pipe railings along the inside of the truss lines are original as are the stamped railing brackets. The floor beams are rolled, and the only apparent alteration to the original design is the addition of outriggers or knee braces to provide lateral stability. Some of the field connections are executed with square-headed bolts. The span is well preserved as is its bucolic setting.

Historical and Technological Significance: The 2-span pony truss bridge is significant because it is a rare and nearly complete example of a riveted, rather than the much more common pin-connected, Pratt half hip bridge. Some of the field connects are done with square-headed bolts, an early-20th century detail that marks the transition from the pin connection to the field rivet connections. Square-headed bolt field connections are not common, but they chronicle the evolution of metal-to-metal connections. Although undocumented in the county engineer's records as to date of construction and fabricator, stylistically the well-preserved span dates to the first decade of the 20th century. It bears design similarities to documented examples of the Dover Boiler Works of Dover, NJ, and it may well be their bridge. The company was active in Hunterdon County during the first two decades of this century according to the Freeholders Minutes.

In addition to being a well-preserved example of the early-20th century bridge technology that combines a popular late-19th century pin-connected truss type with more advanced riveted and bolted connections, the bridge enjoys integrity of setting. Located in a county noted for its picturesque agrarian areas and working farms, the span is well sited in an agricultural area that retains its historic rural character. The setting contributes to the historic significance of the bridge.

Boundary Description and Justification: The bridge is located in a well preserved rural setting. While the span is individually significant, it would also be a contributing recourse should the area be evaluated as a rural historic district. The nearby farmhouse and related farm were not evaluated for National Register eligibility as part of this study.

SETTING / CONTEXT The bridge carries one lane of a lightly travelled country road over a minor stream in a wooded rural setting adjacent to a well-maintained early-19th century farmstead. The setting is unspoiled and contributes to the significance of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed 2-panel pin-connected Fink-like truss bridge bears on random stone abutments with wingwalls. There are minor welded alterations and repairs, but the unusual trusses perform like a Bollman with a floor beam hung from the diagonals. Undocumented as to original date and fabricator, the bridge dates stylistically to ca. 1880 and is the sole known example of its type in the county. It is technologically significant based on the design of the trusses.

INFOR MATION

Bibliography:
Condit, Carl. American Building Art 19th Century. 1960.

Physical Description: The 33'-long, one-span, pin-connected pony truss bridge is a variation of the Bollman truss in which the chief characteristic is that the floor beam(s) are supported by a pair of diagonals which span from end of span to end of span, accomplished in this 2-panel bridge by pairs of loop forged eye bars. Bars in one panel are fitted with a turnbuckle for adjustments. The top chord, end posts, and one vertical appear to be original, although repaired several times. The trusses consist of vertical end posts which are a pair of channels with a full-height cover plate on the approach roadway face and a top and bottom batten plate on the span face. The top chord is made up of a pair of channels with a top cover plate and bottom batten plates. It extended beyond the end post by about 8" and is finished with a decorative cast cover. The top chord is a compression strut that holds the supporting columns (end posts) from falling in to the middle. There are no bottom chord elements. The vertical is a pair of channels with top and bottom battens. The one on the upstream side is a modern replacement. The vertical is a "dummy" member which serves only to halve the unsupported length of the top chord. The rolled I-section floor beam is supported on an inverted U-hanger which passes over the pin connecting the diagonals. The end posts are set on plates on the ashlar abutments. The steel grid deck was placed in 1962.

Historical and Technological Significance: Although undocumented as to date of construction and fabricator, the span is a rare example of a Fink or Bollman truss type where the floor beams are supported by a pair of diagonals that span from end of span to end of span. Originally designed for the combination of wood and iron, the Bollman truss was developed in 1850, and while it increased the possible length of bridges of its day, it passed from favor by 1880 because it is not a rigid truss. Dated stylistically to ca. 1880, the bridge represents the most basic expression of the Fink or Bollman truss form (it is not developed enough to indicate which diagonal pattern it would have been had it been more than two panels long), and it is historically and technologically significant as a rare and fairly complete survivor of the pre-Civil War bridge technology.

SETTING / CONTEXT The bridge carries two lanes of a town street over a minor stream in the architecturally significant 19th-century town of Lambertville. It is on a residential street and is located in the Lambertville Historic District. It is one of three 1870s stone arch bridges in the district over the same water feature (1000056, 100Y041 are the others). The bridge was built within the 19th-century period of significance of the Lambertville Historic District, and it is a contributing resource.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. Lambertville Historic District. 06/30/1983. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed short stone arch bridge, built in 1875, is of rubble-coursed construction with ringstones defining the arch. There is no keystone. Extended stone wingwalls mark the approaches, and stone retaining walls channel the stream. The bridge was repointed in 1957 and 1963. While not individually significant, the well-preserved span reflects Lambertville's transportation history emphasized in the National Register nomination, and it contributes to the historic character of the district.

INFOR MATION

BIBLIOGRAPHY:

Hunterdon County Engineer's Office Bridge card Y41.
Hunterdon County Master Plan: Sites of Historic Interest. 1979.
Schmidt, Hubert G. Rural Hunterdon: An Agricultural History. New Brunswick: Rutgers University Press, 1945.
ONJH. National Register File: Hunterdon County: Lambertville Historic District. 1983.

PHYSICAL DESCRIPTION: The 40'-wide elliptical stone arch bridge with random-coursed ashlar spandrel walls was built in 1875 of the locally common gray granite stone quarried in nearby Raven Rock. It is of traditional construction, using ringstones to define the arch and is finished with low stone parapets and extended wingwalls. The bridge was insensitively repointed with very light mortar in 1957 and again in 1963. It is very similar to another arch bridge a few feet away, over the same meandering stream (100Y041).

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The small stone arch bridge built in 1875 is located in the National Register-listed Lambertville Historic District, recognized for its transportation and architectural significance. Lambertville is a town which was shaped by the transportation needs of the state. Located on the Old York Road from Philadelphia to New York City, its growth surged with the opening of the D&R Feeder Canal in the early 1830s. The Feeder, an important link with industrial Trenton and Philadelphia with the rich eastern Pennsylvania coal fields, carried its peak loads in the 1860s. The town also benefited from the construction of the Delaware Division Canal in Pennsylvania. Canal boats were pulled across the Delaware River by cable to Lambertville, there connecting with the D&R. In addition to the canal feeder, which was open to marine traffic until about 1913, Lambertville was also the site of the main shops for the Belvidere and Delaware Railroad, built from Trenton to Warren County and opened in 1851. The railroad also played a significant role in the 19th and early-20th century development of the community as did the road. CR 518, the road carried by the bridge, is the historic route from Lambertville to Hopewell (Mercer County). Technologically the short span is representative of what by 1876 was common technology. Its significance is that it was built within the 19th-century period of significance of the Lambertville Historic District and that it contributes to the historic and physical character of that district.

Boundary Description and Justification: The bridge is a contributing resource in an National Register-listed historic district. The bridge and its surroundings are significant. For a precise delineation of the Lambertville Historic District boundaries, refer to the National Register file at NJHPO.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The rubble-coursed elliptical stone arch bridge built in 1876, has low stone parapets and wingwalls. The arch is set with rusticated ringstones. The southeast wingwall was reinforced with concrete in 1963, and the spandrel walls have been incompatibly repointed. While not individually distinguished, the bridge reflects the significant transportation history emphasized in the National Register nomination. It contributes to the historic character of the district.

INFOR MATION

BIBLIOGRAPHY: Hunterdon County Engineer's Office Bridge card Y41.
Hunterdon County Master Plan: Sites of Historic Interest. 1979.
Schmidt, Hubert G. Rural Hunterdon: An Agricultural History. New Brunswick: Rutgers University Press, 1945.
ONJH. National Register File: Hunterdon County: Lambertville Historic District. 1983.

PHYSICAL DESCRIPTION: The 40'-wide elliptical stone arch bridge with random-coursed ashlar spandrel walls was built in 1876, as inscribed in a center stone. The stone also identifies the bridge committee members as Levi Reynolds, J.H. Boozer, B. Blackwell, J. Dilts, and P.B. Goodfellow. It is constructed of the locally common gray granite stone quarried in nearby Raven Rock. It is of traditional construction, using ringstones to define the arch. It is finished with low stone parapets and extended wingwalls. The bridge was "patched" in 1950, and insensitive repointing with very light mortar was done in 1963 and 1966. It is very similar to another arch bridge a few feet away, over the same meandering stream (100Y040).

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The small stone arch bridge built in 1876 is located in the National Register-listed Lambertville Historic District, recognized for its 19th-century transportation and architectural significance. Lambertville is a town which was shaped by the transportation needs of the state. Located on the Old York Road from Philadelphia to New York City, its growth surged with the opening of the D&R Feeder Canal in the early 1830s. The feeder, an important link with industrial Trenton and Philadelphia with the rich eastern Pennsylvania coal fields, carried its peak loads in the 1860s. The town also benefited from the construction of the Delaware Division Canal in Pennsylvania. Canal boats were pulled across the Delaware River by cable to Lambertville, there connecting with the D&R. In addition to the canal feeder, which was open to marine traffic until about 1913, Lambertville was also the site of the main shops for the Belvidere and Delaware Railroad, built from Trenton to Warren County and opened in 1851. The railroad also played a significant role in the 19th and early-20th century development of the community as did the road. CR 518, the road carried by the bridge, is the historic route from Lambertville to Hopewell (Mercer County). Technologically the short span is representative of what by 1876 was common technology. Its significance is that it was built within the 19th-century period of significance of the Lambertville Historic District and that it contributes to the historic and physical character of that district.

Boundary Description and Justification: The bridge is a contributing resource to an National Register-listed historic district. The bridge and its surroundings are significant. For a precise delineation of the Lambertville Historic District, refer to the National Register file at the NJHPO.

SETTING / CONTEXT The stringer bridge carries a two lane with shoulders state highway over Stony Brook. It is located in a wooded setting on the edge of a small village of modified 19th- and 20th-century homes. The road carries busy arterial traffic.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed single span concrete encased steel stringer bridge is supported on concrete abutments with concrete wingwalls. It is finished with balustrades with plain posts. The bridge is an uninspired example of the most common bridge type used by the county and the state in the road expansion projects of the post-WW I years. It lacks technological or historical significance.

SETTING / CONTEXT The bridge is located in the quaint town of Lambertville. It carries a busy 4-lane state highway through an area of late-18th and early- to mid-19th century homes, inns and businesses. The bridge is part of the route that bypasses Main Street, the historic main road through Lambertville. It is located within the boundaries of the Lambertville Historic District which encompasses most of the political boundaries of the town.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible. Listed. Lambertville Historic District. 06/30/1983. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The concrete deck arch bridge with concrete balustrades and decorative spandrel panels reflects the apparent local preference for arches. The bridge is an unaltered representative example of the type. One of six arches crossing Swan Creek, together they document arch bridge technology from 1872 through 1929. Although built later than the period of significance of the Lambertville Historic District, it is significant on its own merits as a well-designed bridge by the State Highway Department.

INFOR MATION

BIBLIOGRAPHY:
Schmidt, Hubert G. Rural Hunterdon: An Agricultural History. New Brunswick: Rutgers University Press, 1945.
ONJH. National Register File: Hunterdon County: Lambertville Historic District. 1983.

PHYSICAL DESCRIPTION: The handsome, well-proportioned reinforced concrete elliptical arch bridge is 32' long and 50' wide. It carries a 4-lane road over a minor stream. The spandrel has spandrel panels with a brush hammer finish. The balustrade is a standard design set between paneled end posts inscribed with date and highway route. The position of the end posts is echoed with scored panels on the wingwalls. The span appears to be unaltered.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The well-proportioned reinforced concrete arch bridge is an excellent and well-preserved example of the high quality designs of the Bridge Division of the New Jersey State Highway Department in the years between the two world wars. Under the direction of bridge engineer Morris Goodkind (1888-1968), Chief Bridge Engineer, and Arthur Lichtenberg, Architect, the department was a national leader in the application of aesthetics to bridge design. They also guided the bridge division at its period of greatest production and growth and the establishment of the state highway system as we know it today. The bridge is located in the National Register-listed Lambertville Historic District, recognized for its 19th-century transportation and architectural significance. Although it was built after the period of significance of the historic district, it perpetuates the local preference for arch bridges, and it contributes to the character of the district. It is however, distinguished in its own right.

Lambertville is a town which was shaped by the transportation needs of the state. Located on the Old York Road from Philadelphia to New York City, its growth surged with the opening of the D&R Feeder Canal in the early 1830s. The Feeder, an important link with industrial Trenton and Philadelphia with the rich eastern Pennsylvania coal fields, carried its peak loads in the 1860s. The town also benefited from the construction of the Delaware Division Canal in Pennsylvania. Canal boats were pulled across the Delaware River by cable to Lambertville, there connecting with the D&R. In addition to the canal feeder, which was open to marine traffic until about 1913, Lambertville was also the site of the main shops for the Belvidere and Delaware Railroad, built from Trenton to Warren County and opened in 1851. The railroad also played a significant role in the 19th and early-20th century development of the community as did the road. This bridge is located on the bypass road which did much to preserve the historic character of the community by relieving the traffic congestion in the district.

Boundary Description and Justification: The bridge is individually distinguished, but it is also located within a historic district. Thus the span and its surroundings are significant. For an exact delineation of the boundary of the Lambertville Historic District, refer to the National Register file at the New Jersey Historic Preservation Office.

SETTING / CONTEXT The bridge carries two lanes and shoulders of a highway over Alexauken Creek. Built as State Route 29, the highway bypasses the historic main street of Mount Airy. The southerly side of NJ 179 forms the northerly boundary of the National Register-listed Mount Airy Historic District. The bridge is not within the district and, it is outside the district's 1750-1881 period of significance. It does not contribute to the historic character of the area.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed 3-span concrete encased stringer bridge is supported on concrete abutments and piers, with concrete wing walls and balustrades. Some of the eight steel stringers have lost the concrete encasement. The bridge is an undistinguished example of the bridge type most commonly used by the county and state in the pre-WWII road improvement projects. It was built well outside the 1750-1881 period of significance of the Mount Airy Historic District to the south.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1891 9-panel Howe pony truss bridge is of riveted construction. It rests on bearing plates supported on 1917 concrete abutments with wingwalls. It has timber stringers and deck. The deck is cambered, but not the truss. Three blast plates remain. Knee braces are used at each floorbeam rather than outriggers. The floorbeams are attached to only the inside plate of the bottom chord. The bridge is extremely well preserved, and it is one of the most distinctive early RR spans in the area.

INFOR MATION

Bibliography:
NJDOT Aperture Card Plan File: Conrail 0501/68.99.
Holton, James L. The Reading Railroad The History of a Coal Age Empire. 1989.
Darnell, Victor. Directory of American Bridge Building Companies. 1984.

Physical Description: The 9-panel Howe pony truss bridge is supported on concrete abutments built in 1917 (south) and 1933 (north). The members are wrought iron, and all connections are riveted. Although moved to this location in 1933, the trusses appear to be entirely original. They are of unusual, massive design with the inclined end posts, top chords, and bottom chords of double-web plate each with two angles which connect to a cover plate. At the bottom (open) edge of the web plates of the top chords there are unusual corrugated plate instead of the more common detail of lacing. Each truss panel is composed of two diagonals in the pattern of an X. The tension diagonal consists of four angles in two pairs riveted to the chord web plates outside the line of the double webs. The compression diagonals, which pass through the tension diagonals, consist of four angles in an H configuration with closely spaced lacing in the webs. Except at the first interior floor beam, there are no verticals, but there are knee braces which extend from the top flange of the floor beams to the inside web plate of the top chord. Another unusual detail is the haunched roadway profile which is achieved by varying the floor beam attachment points. At the abutments the stringers sit on a timber bridge seat rest on the back wall which is depressed so that the roadway surface is lower than the bridge bearings. The first interior floor beams are riveted to the underside of the bottom chords while the remaining floor beams frame into the inside web plates of the bottom chords.

Historical and Technological Significance: The wrought-iron Howe pony truss bridge is technologically significant as a rare survivor of its type, being one of the oldest and most complete railroad-related pony truss spans in the state (criterion C). The various plans and shop drawings that survive offer an interesting chronological history of the crossing and the trusses. Prior to 1896 the Easton & Amboy Railroad, a subsidiary of the Lehigh Valley Railroad, had constructed a 3-span timber pony truss bridge over its two-track line. A plan prepared for or by the Easton & Amboy Railroad dated April 4, 1896 shows the addition of a new masonry and timber bent at the line of the original south abutment, and the construction of a new stringer end span that allowed the excavation under the original south end span to accommodate a third track.

The Easton & Amboy line became known as the Lehigh Valley Railroad. In 1916 the LVRR designed a reinforced concrete south abutment and a new timber pony truss bridge that eliminated the short south end span added 20 years earlier. The inscription on the south abutment reads "1917" showing that it was built the year after the date on the plans.

Plans dated March 21, 1933, indicate that the Lehigh Valley Railroad replaced all of the timber pony truss span except the 1917 concrete south abutment. The work was done in 1933 and 1934. The 1917 abutment was raised with a new concrete seat. The north abutment is a gravity type. The most significant feature of the 1933 "upgrading" of the crossing is that the Howe pony trusses installed to replace the timber trusses. The iron trusses were fabricated in 1891 by the Philadelphia Bridge Works. They are a pair of the six "side trusses" fabricated for the LVRR for the "Stanton Bridge" (bridge 53-A) in Hunterdon County. The Stanton bridge was removed and the trusses were in storage. While the trusses are old, the rolled floor beams, stringers, and timber plank deck were new in 1933. The plans show that the floor system was designed for a strong of 15-tone trucks (similar to today's H-15 loading). The 1891 truss lines were checked for this load in 1933 and found to have great excess capacity.

A notation on the 1891 Philadelphia Bridge Company shop drawing specifies that six "trusses like this" were wanted. From the size of the section of the truss members, it is clear that the trusses were built to carry rail traffic, not vehicular traffic. The shop drawings give no material properties, so the note that the trusses are wrought iron is not confirmed. The 1891 trusses survive basically unaltered, and they rank among the oldest and most complete railroad-related pony truss spans in the state.

The Philadelphia Bridge Works was started in 1877 by Cofrode & Saylor. Their shop was located in Pottstown. The 1898 Philadelphia city directory list the owners of the company as C.R. Baird and Company and that the plant was idle and for sale. It was purchased by the Pottstown Bridge Company who subsequently sold to McClintic-Marshall in 1900. The Pottstown works were on the location of a former repair shop of the Philadelphia and Reading (Reading) Railroad.

A. G. Lichtenstein & Associates, Inc. performed initial survery.
NJDOT updated data 03-01-2001.
Correction Updates Etc should be sent to
Correspondence.Unit@DOT.State.NJ.US
November 12, 2002

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The fact that it was moved does not detract from its technological significance. It is the trusses that are the important part of the resource, and the boundary is limited to the trusses themselves.

SETTING / CONTEXT The bridge carries one lane of a lightly traveled country road over the Lehigh Valley Railroad main line in a rural, agricultural setting. The Lehigh Valley Railroad was a Pennsylvania coal hauler that linked with the CRR of NJ at Phillipsburg in 1855. It developed its own line in New Jersey beginning in 1871. The line became part of Conrail in 1976 and is actively used today as a freight route.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel riveted Warren pony truss bridge with original outriggers has floor beams that vary in depth to create the camber. Timber stringers are notched to go over floor beams. The wearing surface is plank. The bridge is supported on ashlar abutments that have been raised twice; concrete caps in 1929, and recent timber grillage. Floor beams were replaced in 1923. The documented, well-preserved bridge is a good, representative example of the truss overpasses from the late 19th century.

INFOR MATION

Bibliography:
Archer, Robert. A History of the Lehigh Valley Railroad. 1977.
NJDOT. Bridge Plan File: 0501/47.52.

Physical Description: The 43'-long and 12'-wide 4-panel rivet connected iron Warren pony truss bridge is supported on rubble-coursed stone abutments. The superstructure has been raised twice to increase vertical clearance. In 1929 new concrete seats were added. The present timber grillage seat is recent. The top chord, bottom chord, and inclined end posts are composed of angles with riveted web plate. What is of particular note are the T sections, set back to back and fixed together with rivets, that make up the diagonals. This detail has been identified on only a few 1890s bridges in New Jersey. The outriggers are built up of riveted plates. The built-up floor beams are fitted with section brackets upon which the timber stringers that are notched to go over the floor beams bear and give the span a vertical deck profile. The wood elements appear to be inkind replacements of the original details. With the exception of being raised, and having modern beam guide rail added, the bridge appears unaltered.

Historical and Technological Significance: The iron Warren pony truss overpass of riveted construction was built in 1890, according to plans drawn by the Lehigh Valley Railroad office of Superintendent of Bridges. It is technologically significant because it is an early and well-preserved example of its type and it has T sections for the diagonals (criterion C). T-shaped section is a ca. 1890 detail that is not common. The riveted Warren pony truss with outriggers to brace the upper chord and provide lateral stability was a common choice by railroads for grade crossing eliminations around the turn of the century, but few of the extant examples are documented as being as early as the Higginsville Road overpass. Additionally, the trusses appear unaltered, and the flooring system appears to be an inkind replacement of the original arrangement of timber stringers carried on brackets on the floor beams carrying a plank deck.

The Lehigh Valley Railroad, primarily a coal hauling line, was completed across eastern Pennsylvania to Phillipsburg, New Jersey in 1855. It connected with the Central Railroad of New Jersey (CNJ) for trackage across the state, but it later built its own line across New Jersey, the Easton & Amboy Railroad. It established its waterfront freight terminals at Perth Amboy in 1875. The railroad is also noted for having purchased the Morris Canal as a means of gaining a trans-state route. The LVRR extended its line to Jersey City beginning in 1887. The railroad survived until 1976 when it became part of Conrail. Much of its historic right-of-way in New Jersey is still an active freight line.

Boundary Description and Justification: The bridge is evaluated as individually significant, and the boundary is limited to the superstructure and substructure of the span itself.

TYPE THRU GIRDER **DESIGN** **MATERIAL** Steel

 # SPANS 1 **LENGTH** 51 ft **WIDTH** 12 ft

CONSTRUCTION DT 1900 **ALTERATION DT** **SOURCE** PLANS

DESIGNER/PATENT CRR NJ OFF. OF CHIEF ENG. **BUILDER** PHOENIX BRIDGE COMPANY

SETTING / CONTEXT The single-span one lane bridge carries unimproved Iron Bridge Road over one line of NJT's Raritan Valley Line track. Originally, the bridge crossed two lines of track. It is located in a wooded hilly setting. The road carries little traffic. The rail line was originally developed by the Central Railroad of New Jersey.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Central Railroad of NJ Main Line Corridor, May contribute.

CONSULT DOCUMENTS SHPO Letter 6/30/95. DOE 11/30/95.

SUMMARY The skewed thru girder with floorbeams bridge is supported on ashlar abutments with wingwalls. Concrete caps have been added to the abutments and wingwalls. The lateral bracing is riveted to the floorbeams. Pipe railings top the girders. Though relatively unaltered, the technology is not innovative, and the bridge is not historically noteworthy. It is a representative example of a bridge type that is common in the state.

SETTING / CONTEXT The one-lane bridge carries an unpaved, 2-lane rural road over the South Branch of the Raritan River. It is located in a wooded rural setting but the urban environment is encroaching. The mill for which the dirt road is named does not appear to have survived, but remains of the dam are visible.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. South Branch Historic District. 01/26/1990. Contributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge is a six panel riveted pin-connected Pratt thru truss bridge. It is supported on rebuilt concrete abutments and stone wing walls. Modifications include welded repairs to bottom chord and verticals and welded gusset panels. Some pins are bent, and the eyebar bottom chord is twisted. Double pins are used for the lower chord at end panel points only. It has original lattice railing. The well-preserved bridge is rated as contributing element in the National Register district nomination.

DESIGNER/PATENT UNKNOWN **BUILDER** WROUGHT IRON BRIDGE CO.

SETTING / CONTEXT The bridge carries a narrow, lightly travelled, unimproved country road over a minor stream in a sparsely developed area. It is located in a wooded rural setting. Within sight of the bridge are the stone abutments of a non-extant railroad bridge. The unspoiled and protected setting enhances the significance of the span.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 11/22/95

SUMMARY The 4-panel pin-connected half hip Pratt pony truss bridge is supported on random ashlar abutments with wingwalls. The diagonals are joined to the chords and through bearing assembly with cast iron connectors, a detail found on another WIBC span in the county (10XXL95). This span is well preserved, and it is one of the most distinctive and complete examples of the over 20 Pratt half hip pony trusses in the county. Its state of preservation and construction details make it significant.

INFOR MATION

BIBLIOGRAPHY:
Darnell, Victor C. A Directory of American Bridge-Building Companies, 1840-1900. Washington D.C.: Society for Industrial Archeology, 1984.

PHYSICAL DESCRIPTION: The four-panel, pin-connected, half-hip Pratt pony truss bridge is supported on random ashlar abutments with wingwalls. The top chord and inclined end posts are riveted box members composed of shallow channels, toe out, with cover plates and widely spaced battens. Vertical members are back-to-back angles joined by lattice. The bottom chord and diagonals are stamped round-headed eyebars. Pin connections are through gusset plates riveted to the vertical ends. An unusual feature is the cast iron bearing shoes with rollers at both the expansion bearing plate and the fixed end. Cast iron connectors are also used for the node connecting the inclined end posts and top chord. The diagonals pass through the node and are secured by bolts. The original lattice railings remain.

Alterations are not intrusive and include the addition of outriggers, small welded reinforcing plates at panel points, duplicate diagonals welded to the outside of the top chords in the end panels, and small repairs. A new deck has been added. The bottom chord appears to be sprung.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: Although the fabricator and date of construction are not documented, the ca. 1895 pin-connected Pratt pony truss bridge appears to be very like the "Low Truss, Half Slope End Posts" bridge described in the 1885 Wrought Iron Bridge Company Illustrated Pamphlet. The castings used at the bearings and the node between the end posts and top chord are unusual construction details that distinguish the span as technologically significant (criterion C). The span, one of over 20 Pratt half hip pony truss bridges in Hunterdon County, is a valuable example of both an important local bridge type and idiosyncratic details. It is attributed to The Wrought Iron Bridge Company based on those details.

The Wrought Iron Bridge Company of Canton, Ohio was founded in 1864 by David Hammond, and it was incorporated in 1871. It operated as such until 1899, when it was absorbed by the American Bridge Company (Darnell, 48.) By the use of illustrated catalogues and through the efforts of traveling bridge agents, distant fabricators were able to successfully compete with local contractors for the county award of bridge contracts. WIBC was one of the most successful late-19th century bridge companies, and their bridges are not uncommon in the state. This example is distinguished by its relatively good state of preservation, integrity of setting, and distinctive details. The modifications do not preclude the span from functioning as originally designed, and they do not outweigh the significance of the seldom-seen details.

Boundary Description and Justification: The bridge is located on an unimproved road in a rural area that was not evaluated for historic district potential. There are no above-ground resources adjacent to the bridge, which is individually distinguished. The boundary is thus limited to the substructure and superstructure of the span itself.

DESIGNER/PATENT FRANCIS C. LOWTHROP **BUILDER** WILLIAM COWIN

SETTING / CONTEXT The bridge, located in the center of the town of Clinton, carries one-way traffic of the main street over the river. It is adjacent to a pond and dam, the Clinton Historical Society, housed in Hunt's Mill built in 1810 (listed in NR 01/74), and the Hunterdon Art Museum housed in Dunham-Perry's Mill listed in NR 4/82). The center is dominated by well-preserved and well-maintained 19th- and 20th century commercial buildings. A bypass highway relieves traffic pressure on the center.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** Yes

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1870 cast and wrought iron Pratt pony truss bridge built by Lambertville contractor William Cowin using the patented design of Francis C. Lowthrop, ranks as one of the historically and technologically significant metal truss bridges in the state. The 2-span bridge with cast verticals and top chord is important in the evolution in materials and design used in bridge building in the mid-19th century transition from wood to iron to steel. The bridge was documented by HAER in 1991-1992.

INFOR MATION

MAIN STREET X SOUTH BRANCH RARITAN RIVER

BIBLIOGRAPHY:

Hunterdon County Engineer's Office Bridge card N1, L-90W, G63.
Hunterdon County Master Plan: Sites of Historic Interest, 1979.
Schmidt, Hubert G. Rural Hunterdon: An Agricultural History. New Brunswick: Rutgers University Press, 1945.
Fleming, R. "Sixty Year Old Iron Bridge in a New Jersey Village." Engineering News Record: November 11, 1920, v35 no. 29 p. 925-927.
Lowthorp, F.C. "On the Use of Cast Iron for Compressive Members of Iron Bridges." New York: Transactions of the American Society of Civil Engineers, v 1, 1872, as read to the Society on June 15, 1870.

PHYSICAL DESCRIPTION: The two span pin-connected Pratt pony truss was fabricated in 1870 by William Cowin as designed by Francis Lowthorp. It uses cast iron for compression members and wrought iron for tension elements. The cast top chord is fitted together with pressure joints. The name of the fabricator is cast into the piece. Diagonals are loop forged eyerods. An unusual feature is the patented Johnson tightener, an eccentric ratchet and pawl arrangement at the panel point for tuning the bridge. Cast vertical members are tapered. Some principal diagonals have a screw adjustment mechanism, but not all. Floor beams are unusual in the use of two rods in an inverted Kingpost truss arrangement which may be adjusted to increase tension. The bottom lateral sway bracing rods screw into a center ring for adjustment. The last segment of the bottom chord is an articulated cast member, designed to absorb temperature expansion and contraction. The vertical cast Italianate column end posts give the date of construction. Sidewalks with decorative cast railings grace each side of the bridge.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The Clinton bridge is one of three remaining bridges constructed by Lambertville fabricator William Cowin, using the design of F.C. Lowthorp (1810-1890). The use of cast and wrought iron reflects a period of experimentation using new materials in bridge construction. Designers were still discovering the strengths and weaknesses of metal, compared to the earlier timber trusses. Emphasis was placed on examining materials under varying stress conditions. Quality control had become an issue.

Lowthorp, who spent at least part of his childhood in Lambertville, was a noted designer of several railroad bridges including a two level bridge across the Delaware River at Easton to connect the Lehigh Valley, the New York Central and the Belvidere and Delaware lines. Lowthorp advocated the use of cast iron in compression, declaring in a paper delivered to the American Society of Civil Engineers, "there is much more to be feared from defects in wrought iron used for tensile than for cast iron used for compressive purposes." Lowthorp's distrust of wrought iron, based on experiments he conducted to test each element before acceptance, were prompted by the inability to control impurities in the metal and the shortage of skilled foundry men.

William Cowin was the fabricator for all three remaining Lowthorp design bridges (N1, L-90W, G63). In addition to these, an Engineering News Record article (11/11/20, p.925) refers to an 1859 cast and wrought iron bridge in Clinton built by William and Charles Cowin. Darnell dates Cowin's production as 1868 to 1870. More research is required to determine if Cowin was involved with the Lambertville Iron Works which also began production in 1859 and operated throughout the century.

Although the village of Clinton has four properties individually listed on the National Register (Clinton Historical Museum 1/08/74, Dunham's Mill-Parry's Mill 4/15/82, Music Hall 5/07/82, and Old Grandin Library 11/01/74), it is not listed as a district. The bridge is located slightly downstream from the mill dams and adjoins the two mill properties. It is an integral aspect of the farm to market cycle which dominated the town's past and a significant element in the character of the present street scape.

The Clinton bridge, based on its age, use of materials, design, and documentation, is one of the most important bridges in the nation. When compared with the other two remaining near-by bridges (one of which, Glen Gardner Pony Pratt Truss Bridge, is on the National Register 9/22/77), it gives insight into the thought processes of the designer and fabricator and the technological imperatives which they faced. The historical context of the bridge remains and has been enriched by the re-use of one mill complex as a historical museum. The

integrity of the site allows insight into daily farm-town transactions and relationships. The size and extraordinary detailing of the bridge reveals civic pride and optimism. The bridge possesses both historical and technological significance.

SETTING / CONTEXT The bridge carries one lane of a quiet rural road over the South Branch of the Raritan River. It is located in a wooded rural setting adjacent to well-maintained 19th-century homes. Green space adjacent to the bridge provides it with a park like setting. The picturesque setting of the bridge contributes to its significance.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 7-panel pin-connected Pratt thru truss bridge is a remarkably complete example of its type. It is supported on random ashlar abutments. The stone wingwalls are topped with pipe railings. Verticals are laced and portals are latticed. Lattice railings remain. Top struts and knee bracing have been reinforced with welded plates. The few repairs noted are unobtrusive and do not compromise the original fabric of the bridge. The nearly unaltered bridge enjoys integrity of setting and design.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office, Bridge Card L140.
Hunterdon County Master Plan: Sites of Historic Interest, 1979.
Darnell, Victor C. A Dictionary of American Bridge-Building Companies, 1840-1900. Washington, D.C.: Society for Industrial Archeology, 1984.

PHYSICAL DESCRIPTION: The seven-panel, pin-connected, full hip Pratt truss bridge is remarkably well preserved. The top chord is composed of channels, toe out and cover plates with lacing. The bottom chords consist of stamped eyebars. Verticals are composed of channels with lacing on each side. The diagonals are stamped eyebars while the counters are rods. The portals are latticed with A knee bracing. Floor beams are hung using U-bolt hangers. The original lattice web railings remain. The bridge is supported on ashlar abutments with wingwalls finished with pipe railings. According to county records, the abutments were repaired in 1967 and the wingwalls were re-pointed in 1975. The corrugated steel deck with asphalt overlay was added in 1970. Lateral bracing has been welded to the top chords, and knee bracing has been welded to each vertical and lateral brace.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The nearly unaltered pin-connected Pratt thru truss bridge is the only documented example of the work of a small New Jersey fabricator, Tippett and Wood (criterion C). According to Victor Darnell, this Phillipsburg (Warren County) firm was established in 1868 and operated until at least 1901. Although the bridge does not exhibit any unusual design details, it is a well-preserved example of an important late-19th century bridge type. Its significance is enhanced by the fact that it is documented as being the work of a little-known local fabricator. The bridge, located adjacent to a well-preserved Hoffman home dating to the 19th century, enjoys integrity of setting and design.

Boundary Description and Justification: The bridge is individually distinguished and it is located in or on the border of a potential historic district. Thus the span and the area adjacent to the abutments is significant. The limits of the potential historic district were not defined in this survey.

SETTING / CONTEXT The bridge carries one lane of a lightly travelled unimproved road over the South Branch of the Raritan River in a picturesque wooded rural setting adjacent to a small park. The road is near a village of well-maintained 19th-century houses adjacent to the railroad tracks. In 1880, when the bridge was constructed, the village of Stanton Station included a church, a store, a post office, a school, and the railroad station a mile distant.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The light pin-connected Pratt thru truss bridge built in 1880 by the Cleveland Bridge & Iron Co. is one of the earliest metal truss bridges in the county. It is well-preserved, complete with its original built up floor beams and well-detail plaque with ornate sunflower motif and scrollwork. The few alterations, which include replacement of one floor beam, end panel points reinforced, and bracing of the verticals, do not detract from the technological and historical significance of the span.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office, Bridge card RQ179.
Hunterdon County Master Plan: Sites of Historic Interest, 1979.
Simmons, David. "The King Iron Bridge and Manufacturing Company." IA The Journal of the Society for Industrial Archeology. Vol. 15, No.2 (1989). pp. 23-39.

PHYSICAL DESCRIPTION: The eight-panel, pin-connected, Pratt half-hip thru-truss bridge is supported on random ashlar abutments. The top chord is composed of shallow toe-out channels and cover plate with lacing. The bottom chord consists of stamped eyebars. Verticals are channels joined with lacing. Top lateral bracing is also angles joined with lattice and reinforced with latticed corner brackets. The vertical hangers have been reinforced with additional welded bars with battens. Floor beams are hung from U-bolt hangers. A noteworthy detail is the original built-up "fish-belly" shaped floor beams. The easternmost floorbeam has been replaced. Expansion is accommodated at the eastern end by roller nests. A crested scrollwork three-dimensional plaque identifies the builder and date. The ornate plaque is decorated with sunflowers and acanthus leaves. Many of the members retain their shop numbers to aid with erection. Alterations on this early bridge are minimal. In addition to the replaced floor beam, other modifications include replaced stringers, a new railing system added, and prior to 1940, horizontal mid-line reinforcing added. In 1960, the end posts, originally composed of toe-out channels joined by lattice or lacing on the top face, were modified. The lattice or lacing was removed, and the channels were joined by welded face plate.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The 1880 bridge ranks not only as one of the oldest thru truss spans in the county, it is also extremely well preserved and exhibits unusual construction details like the built-up "fish belly" floor beams (criterion C). It was manufactured by the Cleveland Iron Bridge and Manufacturing Company, incorporated by founder, Zenas King of Cleveland, Ohio. King, who had worked as a salesman for Thomas Moseley selling Moseley's patented bowstring truss bridge before establishing his own firm about 1860, initially marketed a patented tubular bowstring trusses, and he was enormously successful from a business standpoint. His bridges were marketed nationally through a network of regional salesmen. His bridges were located in every state. The bridge pieces were fabricated in his Cleveland shops and shipped to the site for erection. Although King's operation was not unlike other bridge companies, he was noted for having an efficient design and operation which made his spans economical -- often the primary reason for selection of a design and fabricator. By the 1880s King had a complete bridge plant and 360 employees and was considered one of the major plants in the country. As the Pratt truss gained in popularity in the late 1870s, it came to dominate as the truss type of choice, and much of King's production in the 1880s and 1890s was the Pratt truss. King died 1892, but the company continued under the direction of his sons, but it was never as prolific as it has been under Zenas.

The bridge, the second oldest extant thru truss span in the county, stands in a remarkably complete state of preservation, especially considering its age. Of particular significance are the built-up floor beams and the elaborate makers plaque. It is one of the few documented examples of the King Iron Bridge and Manufacturing Company in the county, and in addition to documenting the evolution and application of metal truss bridge technology in Hunterdon County, it also documents how those bridges were built.

Boundary Description and Justification: The bridge is not located in a potential historic district. The bridge is individually distinguished and the boundary is limited to the substructure, including wing walls and superstructure.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1878 iron pin-connected 9-panel Pratt thru truss bridge supported on ashlar abutments is constructed with patented Phoenix columns. It ranks as one of the most important thru truss bridges in the state based on its age, nearly complete state of preservation, and use of Phoenix columns for the compression members. Alterations are minimal and non-intrusive. The bottom lateral bracing joins to a center ring, like the 1870 Clinton bridge (10XXON1), also fabricated by the Lambertville Iron Works.

PHYSICAL DESCRIPTION: The single span, cast- and wrought-iron, pin-connected Pratt thru-truss bridge is supported on ashlar abutments with flared wingwalls. The trusses consist of inclined portals, top chords, and intermediate verticals, or posts, of patented Phoenix column sections which are joined at each panel point with cast iron pieces that are compression fittings. Inside each piece is a sleeve over which the column section fits. The connecting pins pass through these castings. The bottom chord and principle diagonals are eyebars which are unusual in having a nearly square cross-section as opposed to the more common rectangular cross-section. The counters are rods with loop forged eyes. They also have sleeve nuts for adjustment. The original vertical hangers are eyebars with loop forged eyes. The vertical hanger pin that carries the U-bolt to accept the floor beam also passes through a special casting which supports the bottom chord. The eyebars of the bottom chord continue through this panel point without connecting to the pin, and the two-pronged, bracket-like casting prevents the 2-panel long eyebars from sagging or moving out of position. The top chord lateral bracing system consists of transverse I-section members and X-pattern lateral bracing rods all of which terminate in an upward extension of the top chord node. The bracing connection is topped with an elaborate ball and spire finial. The portal bracing contains decorative cast-iron filigree at the corners. The expansion bearings are probably nested rollers but they are completely obscured by the bearing casting.

Some of the steel stringers and corrugated metal deck are modern. Welded steel braces have been added from the portals diagonally to the bottom chord first panel point, as well as welded knee braces between the verticals and top lateral braces. Welded steel gussets are added to the top and bottom pins of the vertical hangers at the first panel points, with two welded bars added to strengthen the hangers. The remainder of the truss is in original condition. The rolled I-beam floor beams have been strengthened with welded top and bottom cover plates.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The nearly unaltered pin-connected Pratt thru truss bridge is a well preserved example of its type and is technologically distinguished as one of the earliest and most complete bridges built with Phoenix columns in the state. It is also the work of one of the county's foremost second-half of the 19th-century foundries, that of William Cowin. Cowin was the fabricator of the most important 19th century bridges in the region.

The Phoenix column, a wrought iron segmental channel riveted together to form a tube of great compressive strength, developed in 1864 by David Reeves of the Phoenix Iron Company at Phoenixville, Pennsylvania. The patented section was used by both the Phoenix Bridge Company and other fabricators in the erection of buildings as well as bridges. By joining the compressive members through compression fittings at cast iron nodes, the Phoenix column "was a great factor causing the substitution of wrought iron for cast iron in compression members of pin-connected bridges," according to noted engineer and author J.A.L. Waddell. The handsome bridge at Raven Rock Road records not only the use of the wrought iron Phoenix column, but also the numerous cast iron elements which serve both utilitarian and decorative purposes. It is an excellent representative of the skill of the 19th-century iron worker

The bridge was fabricated by the Lambertville Iron Works, a local foundry which began operation in 1849 as Laver & Cowin, and it continued in operation through most of the second half of the nineteenth century (Schmidt, p. 219). The name was changed to Lambertville Iron Works by 1878, as attested to by the plaque on this bridge, and it was run by William Cowin who is associated with not only this bridge but the three cast and wrought iron spans designed by engineer Francis C. Lowthorp and built in Clinton, Glen Gardner, and Hampton between 1868 and 1870. Cowin's foundry was also making axles, safety boilers, and steam engines (Snell, p. 283).

The bridge enjoys integrity of setting and is located in a rural area near two well-preserved early farmsteads on a road joining the nearby

villages of Raven Rock and Rosemont. Raven Rock, an area of quarrying industry, was serviced by the New Jersey Railroad, the Delaware & Raritan Canal, and a covered bridge across the Delaware River. In 1880, it boasted a railroad station, a store, a post office and several dwellings. Rosemont was settled in 1754.

SETTING / CONTEXT The bridge carries a lightly traveled country road over a minor stream in a wooded setting on the edge of the village of Locktown. An 18th century meeting house and 19th century school house are within sight of the bridge, but not close enough to be evaluated as part of any potential historic district.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Historic District. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The undocumented ca. 1920 riveted Warren with verticals pony truss bridge is supported on one stone abutment and one concrete. The built-up box top chord and end posts are composed of channels turned toe in with cover plate. The original pipe railings remain. Alterations include bolted extensions of floor beams. The bridge was moved from Lambertville when the 1899 WIBC Pratt pony truss at this crossing was lost. One of over 25 Warren pony trusses in the county, this example is undistinguished.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The pin-connected Pratt thru truss bridge is supported on ashlar abutments with wing walls. A noteworthy feature is the basket-like 4-pronged end on the hip vertical floorbeam hangers. The bottom chord is composed of loop forged eyebars with erection numbers. Minimal additions include plates welded to floor beams and diagonal top chord bracing. The bridge is significant because it is relatively unaltered, documented, in its historic context, and has distinctive design details.

INFOR MATION

BIBLIOGRAPHY
Hunterdon County Engineer's Office, Bridge card D481.
Hunterdon County Master Plan: Sites of Historic Interest, 1979.
Simmons, David. "Bridge Preservation in Ohio." Cities & Villages. Vol. XXVI No. 8 (August, 1978), pp. 13-18.

PHYSICAL DESCRIPTION: The single-span pin-connected Pratt thru-truss bridge is supported on random ashlar abutments with U-type wingwalls. The trusses appear to be original with the exception of the floor beams, stringers and deck that have been recently replaced, the addition of welded corner braces to the top laterals, and welded braces extending from the portal struts to the exterior floor beams. The trusses are pin-connected throughout. The portals and top chord consist of two channels, a cover plate and lacing. The intermediate verticals consist of two channels with lacing. The lacing on the verticals parallels the bridge centerline. The bottom chord eyebars and diagonal eyebars have forged eyes. The counters are provided with sleeve nuts for adjustment. The end panel vertical hanger has a four-prong, claw-like ends which engage the pins directly over and in line of the U-bolt floor beam hanger. Such an arrangement, also seen on King Bridge Company spans from the same era, means that the hangers are out of phase or reversed. The expansion bearings consist of nested rollers.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The well preserved 1897 thru-truss bridge is a documented example of the work of the Wrought Iron Bridge Company of Canton, Ohio, one of the most prolific late-19th century bridge fabricating concerns in the country. In addition to its historical association with the WIBC, the span exhibits unusual details, including the "crows foot" vertical hanger detail and the reversed vertical hangers . A good representative example of an important 19th-century bridge type (criterion C), the span enjoys integrity of setting and is located in its original industrial context adjacent to a water-powered saw mill. The saw mill, which is still in operation, is known to have been owned by Enoch Danbury before 1891. Thus the bridge embodies both integrity of design and setting.

The Wrought Iron Bridge Company (WIBC) was organized in 1866 by David Hammond and incorporated in 1871. It is one of the three Ohio bridge companies that stand out for their designs and technological contributions to bridge engineering (Simmons, p. 15). The company distributed, through a network of regional agents who submitted both design and price to the Freeholders, a variety of truss types from the bowstring truss through the Pratt truss. Many of their notable details were castings to join various members of the truss. WIBC was absorbed by the American Bridge Company in 1899.

Boundary Description and Justification: The bridge is located next to a potentially historic saw mill, but the span is distinguished on its own merits. The history of the two structures appears to be independent. The significant boundary of this resource is limited to the substructure and superstructure.

SETTING / CONTEXT The bridge carries one lane of a quiet country road over the Musconetcong River, the boundary between Hunterdon and Warren counties. It is located in a rural setting, adjacent to a well-maintained 19th century farm with fields and outbuildings. Other bridges in the county by the same fabricator include 10XXF48.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible.
CONSULT DOCUMENTS SHPO Letter 11/22/95

SUMMARY The 2-span pin-connected half hip Pratt pony truss bridge is supported on random stone abutments. The pier was rebuilt in concrete in 1988. Each span is 4 panels, and alterations are minimal. Plates have been welded to the lower chord on one side, and welded repairs have been made to the bearings on the pier. The undated span is one of several by the Dover Boiler Works, active in the county through 1919. This is a representative example of a common local bridge type and was fabricated locally.

INFOR MATION

Bibliography:
Platt, Charles. Dover Dates 1722-1922. 1922.
New Jersey Bureau of Statistics Department of Labor. The Industrial Directory of New Jersey. 1912-1952.

Physical Description: The 2-span pin-connected Pratt half hip with counters pony truss bridge is supported on stone abutments. The concrete pier was placed in 1988. Each of the trusses is 5 panels long and has round-headed eye bars for the lower chords. Floor beams are hung from the lower panel points by a pair of U bolts. The most unusual detail is design of the built-up verticals composed of back-to-back angles with a flared web plate. The flared shape adds lateral stability. Repairs are minimal. Plate has been welded to the inclined end posts at the bearings. One line of the original pipe railing survives, but the other, at the lower level, has been replaced with modern beam guide rail.

Historical and Technological Significance: The undocumented 2-span pin-connected Pratt half hip pony truss bridge is technologically significant as a representative example of a once-common bridge type and for the unusual design of the verticals. The flared shape provides a braced member and lateral stability, an inherent weakness in pony truss bridges. Historically the span is important for its association with a regional fabricator, The Dover Boiler Works of nearby Dover (Morris County). The company, which produced a variety of metal products including boilers, hoppers, bins, stacks, and later structural steel, was established in 1874 by Foster F. Birch as a small repair shop only doing hand-repair work. By 1927 the company, then lead by Birch's son William F. Birch, employed 156 men and 5 women. Their products, made from steel purchased from any number of sources like Bethlehem and Luken Steel, went all over the world. Their boilers were in the Woolworth Building in New York. Bridges were not the firm's main product, but they are documented as serving as bridge fabricators from about 1900 through 1919. They, like other small metal fabricating shops, cut, shaped, and riveted angles, channels, and plate into bridges to service the local market. The Dover Boiler Works bridges are concentrated in northwest New Jersey. The company was in business in Dover as late as 1953 under the name Dover Boiler Plate and Fabrications, but its output was considerably less than its 1920s and 1930s peak.

DESIGNER/PATENT UNKNOWN **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge carries one lane of a heavily trafficked rural road over the South Branch of the Raritan River. It is located in a sparsely developed area immediately south of NJ 31 that is currently undergoing modern development. The setting does not contribute to the significance of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Bridge was Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 7-panel pin-connected Pratt truss bridge is supported on random ashlar abutments with wingwalls. It is a well-preserved example of its type, and it retains its original pipe railing. Although there is some impact damage to the toe-out laced verticals, alterations to the bridge are minimal. The fabricator is not documented, but the state of preservation makes the span one of the more complete of the 10 Pratt thru trusses spans in the county. It is significant as a good example of its type.

INFOR MATION

Bibliography:
Hunterdon County Engineer's Office. Bridge File: C 76.

Physical Description: The well-preserved 102'-long pin-connected Pratt thru truss bridge is supported on ashlar abutments. The top chord and inclined end posts are composed of toe-out channels with cover plated riveted to the top and battens on the bottom. The portal brace and brackets have a lattice fill, and the bridge plaque is affixed to the top strut. The verticals are also toe-out channels, joined on each face by lacing. The bottom chord is made up of stamped, round-headed eye bars, and the diagonals are loop forged eye bars. Interestingly, the floor beams are connected to the lower panel point pins by punched plate hangers connected to the floor beams by rivets rather than the more common inverted U hangers that pass over the pin. The lateral and sway bracing appear to be original. The bridge has impact damage, modern beam guide rail on the inside face, and small welded repairs, but overall it is in a remarkably complete state of preservation.

Historical and Technological Significance: The 102'-long pin-connected Pratt thru bridge was built in 1893, but the designer and fabricator are not known. While exhibiting no patented details, its significance is as a very well-preserved example of a technologically and historically notable bridge type that is becoming increasingly rare in New Jersey (criterion C). It is one seven Pratt thru truss bridges from the 19th century in the county, and all were evaluated as significant either individually or as part of historic districts. Its technological significance is enhanced by the fact that the floor beams are hung from the pins by punched plates riveted to the floor beams rather than the more common 1890s detail of suspending them from inverted U bolts that pass over the pins. The bridge plaque identifies the date of erection and the Freeholders.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to substructure and superstructure of the span itself.

DESIGNER/PATENT UNKNOWN **BUILDER** DOVER BOILER WORKS

SETTING / CONTEXT The bridge carries one lane of a narrow road over a minor stream. It is located in a wooded setting near open fields adjacent to a village of 18th- and 19th-century stone houses, barns and an early mill. The village of Kingtown has historic district potential, and the bridge contributes to the historic character. The period of significance of the potential historic district appears to extend through at least the first decades of the 20th century.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Potential Kingtown Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The skewed 4-panel Warren with verticals pony truss bridge is riveted construction and is supported on random ashlar abutments and stone wingwalls. Concrete caps have been added. Riveted outriggers are part of the original design. Minor welded repairs do not compromise the design integrity. It is the latest example of a truss bridge constructed by New Jersey's Dover Boiler Works in the county and is eligible for listing in the National Register of Historic Places under Criterion C. The bridge would also be a contributing element of a Kingtown Historic District under Criteria A and C should such a district be found eligible in the future.

INFOR MATION

Bibliography:
Beers, Comstock & Cline. Hunterdon County Atlas. 1873.
Platt, Charles. Dover Dates 1722-1922. 1922.
Hunterdon County Engineers Office. Bridge file F48.

Physical Description: The 50'-long, 4-panel, riveted Warren pony truss bridge is supported on random ashlar abutments, and the trusses are composed of angles set back to back. The asymmetrical gusset plates are plate set between the angles. The floor beams and stringers are rolled I sections. Outriggers are built up, and they are original to the span as is the line of pipe railings on the inside of the trusses. The pipe is held by stamped brackets. The lower line of pipe railing has been replaced by modern beam guide rails. Both the bridge and its setting on the south edge of the village of Kingtown are well preserved.

Historical and Technological Significance: The small settlement of Kingtown in Franklin Township is historically and architecturally significant as a well-preserved example of an 18th and 19th century crossroads community that grew up around several water-powered mills. In 1873 it consisted of about 10 buildings that included a grist mill and a blacksmith shop. Today stone houses and a nice assemblage of farm-related buildings survive to chronicle the agrarian heritage of the area. The small enclave of buildings appears to be a potential National Register historic district with the 1919 Dover Boiler Works bridge as a contributing resource.

In addition to its historic association with a potential historic district, the span is a well-preserved example of the work of a local fabricator, the Dover Boiler Works of Dover (Morris County). Established in 1874 as a small repair shop doing hand work, it developed into an albeit small but internationally represented producer of stacks, boilers, hoppers, and related metal equipment for the materials handling industry. Locally it fabricated bridges out of steel purchased from any number of American mills including Bethlehem and Lukens. Their bridges are documented in northwest New Jersey from about 1900 until 1919. The Upper Kingtown Road bridge is a late but complete example of the company's work.

Boundary Description and Justification: The bridge appears to be a contributing resource to a potential historic district with a period of significance through the first two decades of the 20th century. Capoolong Creek appears to be a boundary of the district. The bridge, substructure and superstructure, and the west approach appear to be within the potential historic district.

Hagely Museum & Library. Phoenix Bridge Co. records.

PHYSICAL DESCRIPTION: The two-span, cast- and wrought-iron pin-connected Pratt pony truss bridge survives in a remarkably complete state of preservation. The trusses and floor beams are original and unaltered. Each five panel truss consists of Phoenix column section top chords and inclined end posts. All of the truss verticals are built up from a pair of angles with lacing rather than Phoenix sections. The pins at both the top and bottom of the verticals pass through the gusset plates. Because the verticals are not Phoenix sections, the cast connecting pieces at the intermediate chord panel points are not needed. At these locations, the pins pass through the walls of the Phoenix section. Castings are present at the top chord/end post connections and the bottom chord/end post connection, or feet. The expansion bearing feet sit on nested rollers, a standard period detail. The bottom chord consists of round-headed eyebars. The principal diagonals consist of needle-headed eyebars. The counters are rods which thread into devises at both ends which pass around the pins. The floor beams are built up from a web plate with four riveted flange angles. The two top flange angles extend out to form part of the knee brace at each vertical. The floor beams hang from the bottom chord pins on U suspenders. All bridge components are stamped with the order number. The spans bear on stone abutments and a mid-stream pier.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The well-preserved 2-span 1885 pony truss bridge is historically and technologically significant as an example of the a Dean & Westbrook built Phoenix-section bridge (criterion C). The use of the Phoenix section without all of the castings at the nodes (panel points), as in this truss design, represents a transitional stage where the Phoenix truss system was being simplified to be competitive with "standard" pin connected trusses of built-up members. The bridge is one of four Phoenix-section pony truss spans in the state.

The patented Phoenix column, developed in 1864 by David Reeves of the Phoenix Iron Company at Phoenixville, Pennsylvania, "was a great factor causing the substitution of wrought iron for cast iron in compression members of pin-connected bridges," according to noted engineer and author J.A.L. Waddell. It enjoyed tremendous popularity in the 1870s and 1880s, and was one of the most important details in the general acceptance of metal truss bridge technology in those decades. In the earliest days, Phoenix-section bridges were designed by, marketed by, and erected by the Clarke, Reeves Company, a separate company with some of the same owners as the Phoenix Iron Company. They primarily built railroad bridges. In 1884 Clarke, Reeves & Company was reorganized as the Phoenix Bridge Company, and in 1885 it entered into an agreement with Dean & Westbrook of New York City for the marketing and erection of highway bridges with Phoenix-section compression members. The agreement was in effect until 1895. After that date few metal truss bridges with Phoenix sections were built. Dean & Westbrook built at least 70 bridges with Phoenix sections in New Jersey, and about 10 survive. The bridge is the only documented 2-span Phoenix column span in the state. It enjoys integrity of design and setting.

Boundary Description & Justification: The bridge is evaluated as individually distinguished. The boundary is limited to the substructure and superstructure.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 3-span (50'-long spans) riveted Warren with verticals pony truss bridge is supported on random ashlar abutments with wingwalls and piers. It is composed primarily of angles, and the riveted outriggers are original, as is the pipe railing. The only alterations appear to be toe walls added to the piers, concrete seats, and encasing the west abutment. Although the bridge is a late example of its type, it is will preserved and the 3 span configuration demonstrates the adaptability of truss bridges to diverse sittings. This adaptability contributed to the popularity, marketability, and continue use of this bridge type and hence, to its significance. It is individually eligible for listing in the National Register under Criterion C.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The riveted Warren pony truss bridge is supported on random stone abutments, pier and wingwalls. The bottom chord is toe-out angles with battens. Lacing joins the toe-down angles of the diagonals. Alterations include a new detail where new floorbeams are supported by rods bolted to brackets welded to original gusset plates and concrete repairs to the substructure made in 1989. A documented but altered example of a field-riveted bridge by a notable fabricator, it has no distinguishing details.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed 5-panel pin-connected 1885 Pratt thru truss bridge is supported on random ashlar abutments and has Phoenix columns for the compression members. The Phoenix section members are joined by compression fittings into cast iron nodes at the panel points. Shop marks and numbers are cast into all parts. The well-preserved bridge, one of the earliest known examples of Dean & Westbrook of NYC, is historically and technologically significant. It is the only skewed Phoenix section span in NJ.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office, Bridge card F82.
Waddell, J.A.L. Bridge Engineering. New York: John Wiley & Sons, Inc., 1925.
Darnell, Victor C. A Directory of American Bridge-Building Companies, 1840-1900. Washington, D.C.: Society for Industrial Archeology, 1984.
Hagley Museum & Library. Phoenix Bridge Company Papers.

PHYSICAL DESCRIPTION: The skewed, single-span, Pratt thru-truss bridge is pin-connected and consists of Phoenix column sections for the portals, top chord and intermediate verticals. The bottom chord consists of circular-headed eyebars. The principal diagonals and end panel hangers consist of needle-headed or loop forged eyebars. The counters consist of rods with clevis which engage the pin at either end for adjustment. All connections except the vertical hangers consist of individual castings which receive the Phoenix- column sections on a flanged lip, and through which the pins pass. At the bearings the castings include integral bearing plates. The expansion bearings sit on nested rollers. The abutments consist of large rusticated ashlar masonry, with flared wingwalls. All pieces are marked with the order number of this span.

A peculiar feature of this bridge is the manner in which the skew of the abutments was accommodated within the truss framing. All floor beams are perpendicular to the bridge centerline with the unequal panel length due to the skew taken up in the end panels. On this bridge the incline of the portals were kept parallel and the end panel of the top chords are of unequal length. This arrangement causes the top chord pins at the end panel points only to be offset from the bottom chord pins so that the end panel hangers are inclined. On the opposing sides are hanger inclines toward the support, while the other hanger inclines toward the floor beam.

Alterations/modifications to the span are minimal and primarily non-intrusive to the original design. The stringers and deck have been recently replaced with a longitudinal laminated timber deck with an asphalt wearing surface. Timber railings have also been added on the inside face of the trusses. The original railings are gone. The intermediate floor beam hangers were strengthened by the addition of a welded "collar" around the Phoenix column section and an additional pair of rod hangers. That work is believed to have been done in 1958, according to county records.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The 1885 bridge is historically and technologically significant as a well-preserved example of 19th-century bridge technology in both its design and its construction details (criterion C). The pin-connected Pratt truss became the most successful and technologically important of the late-19th century metal truss types. What distinguishes this cast- and wrought-iron example is the use of Phoenix section columns and cast nodes for connection of the Phoenix-section elements and the way the skew of the abutments was accommodated within the truss framing. Its historical significance is increased by the fact that it is a documented example of the work of New York City-based fabricator Dean & Westbrook, a firm that took over the erection of highway bridges through a contractual arrangement with the Phoenix Bridge Company of Phoenixville, PA. Dean & Westbrook built highway bridges with Phoenix columns until 1896. The Lower Lansdowne Road bridge is one of about ten bridges in New Jersey that are built with Phoenix sections between 1878 and 1895. All are evaluated as significant due to the presence of the important patented Phoenix section, a detail that did as much as any other to promulgate the acceptance of metal truss bridges in the 1870s and 1880s.

The Phoenix column was developed in 1864 by David Reeves of the Phoenix Iron Company at Phoenixville, Pennsylvania. It is composed of at least four segmental wrought channels whose flanges were riveted together to produce a circular section with great compressive strength. The Phoenix column, and its cast iron connecting pieces for compression fittings of the various elements, also designed and patented by Phoenix Iron Company engineers, "was a great factor causing the substitution of wrought iron for cast iron in compression members of pin-connected bridges," according to noted engineer and author J.A.L. Waddell. They reflect the then-current understanding of tensile and compressive forces at the panel points.

The bridge is one of three bridges with Phoenix sections, each of a different design, in Hunterdon County. Two of them were built by Dean and Westbrook, the fabricating firm based in New York City that was established in 1885, the same year they entered into an agreement with the Phoenix Bridge Company to act as agents for the construction of Phoenix-column highway bridges. From 1885 until 1895, Dean

& Westbrook built over 280 Phoenix column highway bridges from Main to North Carolina, but most of their activity was in New York, New Jersey, and Pennsylvania. They built over 70 in New Jersey alone, and they remain in Mercer, Bergen, Somerset, Hunterdon, and Monmouth counties. This is the only skewed thru truss bridge. Correspondence in the Phoenix Iron Company records preserved at the Hagley Museum and Library reveals that when this bridge was ordered, the wrong skew connecting pieces were shipped to the site. The error was not discovered until the bridge was being erected. The correct connecting pieces had to be ordered from Phoenixville.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. The boundary is limited to the substructure and superstructure of the span.

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 5-panel Pratt pony truss pin-connected bridge bears on random ashlar abutments. The bottom chord is composed of stamped eye bars. 1991 alterations included welded reinforcing plates on floorbeams and a new flooring system with a glulam deck. Otherwise the trusses are well preserved. Lattice web railings with center medallions remain. The span is significant as a good example of its type and as an example of the work of the Groton Bridge Co., a NY fabricator not well represented in the state.

INFOR MATION

Bibliography:
Thurber, Pamela. "The Groton Iron Bridge Company." Historic Ithica and Tompkins County Newsletter. Fall, 1983.

Physical Description: The 5-panel full hip pin-connected pony truss bridge is supported on ashlar abutments. It has some small reinforcing elements added at the panel points, but most of the original fabric survives, including the lattice railing with decorative bosses on the bridge and atop the low stone walls of the approaches. The top chord and inclined end posts are composed of toe-out channels with a top web plate and battens on the bottoms. The verticals are back-to-back angles with a laced web. The connection of the verticals to the panel points is by a plate riveted, bolted, or welded to the angles. Diagonals and the bottom chord are made up of stamped, round-headed eye bars while the counters are loop forged bar stock. The rolled I-section floor beams are hung from the bottom panel points by u-hangers. The bridge exhibits no unusual construction details. Modifications to the original design include outriggers connected by welds and splice plates to the floor beams and top chord and a wood laminated deck added in 1991.

Historical and Technological Significance: The pin-connected Pratt pony truss bridge, built in 1896, is a well-preserved example of a historically important bridge type. One of over 10 examples of the bridge type in Hunterdon County, which is distinguished with having more 19th-century truss bridges than any other county in the state, this span is historically noteworthy because it is a documented example of the work of the Groton Bridge Company of Groton, New York. It is one of less than six documented examples of their work in the state.

Groton is located on a spur of the Southern Central Railroad that was opened in 1869 linking the small town near Ithica with routes to Canada and Pennsylvania coal region. In 1877, two small agriculture-related businesses, the Groton Iron Works, a blacksmith shop, and the Groton Separator Works, a manufacturer of farm implements, merged in 1877 to form the Groton Bridge Company. The firm was established to take advantage of the rapidly increasing metal truss bridge market that was developing as county after county set about improving and upgrading their roads. The company grew and prospered, becoming one of the largest employers in the community and building bridges in at least 27 states. Between 1877 and 1887, the firm built mostly small pony truss bridges in upstate New York. In 1887 the operation was expanded and the product line increased to include larger bridges. It was during this expanded phase of the company's operations that the bridge in Glen Gardner was built and finished with the distinctive demilune plaque atop each top chord. In 1900 the company was absorbed into the new American Bridge Company. The company continued its operations until the 1920s. It also produced structural steel.

The history of the Groton Bridge and Manufacturing Company is reflective of the era during the late-19th century when a host of small companies recognized the economic advantage of designing and manufacturing metal truss bridges as the nation embarked on its most ambitious road improvement campaigns. The era of individual companies, represented regionally and/or nationally by local sales people, was brought to a close in 1900 with incorporation of J.P. Morgan & Company's American Bridge Company, a conglomerate made up of 24 companies that represented half the nation's bridge fabricating capacity. Some plants were closed, and others, like Groton's works, continued in operation.

Boundary Description and Justification: The bridge is evaluated as individually distinguished. Its setting does not appear to have historic district potential. Thus, the boundary is limited to the substructure and superstructure of the span itself.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 1870 Pratt pony truss bridge of wrought and cast iron was built by Lambertville contractor William Cowin, using the design of Francis C. Lowthrop. It is one of 3 Cowin/Lowthrop spans extant in New Jersey. The others are 10XXON1 and 2102225, but this is the least altered of the three. It is an extremely significant early example of metal truss bridge technology. The span is of national importance. It was sensitively rehabilitated, including a new flooring system, in 1992.

DESIGNER/PATENT UNKNOWN **BUILDER** G M RUSLING, HACKETTSTOWN

SETTING / CONTEXT The bridge carries one lane of a narrow street over the Musconetcong River, the border between Hunterdon and Warren Counties. The street is in the center of the well-preserved 19th-century village of Finesville which has National Register-historic district potential. The bridge contributes to the historic character of that potential district. The bridge is a few feet downstream from a mill dam. The mill, now converted to housing, remains.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No
CONSULT STATUS Individually Eligible. Agreed Potential Historic District. Contributing.
CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 8-panel pin-connected Pratt thru truss bridge is supported on random ashlar abutments. The floorbeams appear to be original. Welded alterations are minimal and include plates at the lower panel points, cover plate on the end posts, and lateral bracing strengthening. The bridge is the only known example of the work of bridge builder G.M. Rusling of Hackettstown. In addition to its historical significance, it contributes to the character of a potential district.

INFOR MATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office: County bridge card H64W. Hunterdon County Master Plan: Sites of Historic Interest 1979.

PHYSICAL DESCRIPTION: The eight-panel full hip Pratt thru-truss bridge has a plaque located at the center of the portals identifying the builder and the Hunterdon County Bridge Committee members. The pin-connected bridge is supported upon stone abutments with retaining walls. The top chords and inclined end posts are box members composed of shallow toe-out channels and cover plates with battens. The bottom chord consists of stamped eyebars, to which reinforcing plates have been welded at the panel points. The vertical members are composed of angles with lacing. The portal braces are also composed of angles with lattice. All but the first interior floor beams are hung from U-bolts. The floor beam hangers are forged loop eye bars that have been reinforced by the addition of bars welded to the top chord and the panel point reinforcing plate. Knee braces have been added at lateral struts and portals. Channel end diagonal braces have been added, and cover plates have been welded to the end posts. According to county records, the corrugated steel deck with asphalt overlay was installed in 1958. Some elements are stamped "Passaic R.M. Co.".

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The date of construction of the 8-panel pin-connected Pratt thru truss bridge is not documented, but stylistically it appears to be circa 1890. The fairly well preserved bridge is the only known example of the work of G.M. Rusling, a New Jersey fabricator. In addition to being a good example of an important bridge type and the work of a local fabricator, the bridge is located in the village of Mount Joy, a potential National Register Historic District. It is a contributing resource in that potential historic district. The first house was reportedly erected in 1829 in what was a saw mill and iron ore mining area. The village preserves its historic, 19th- and early-20th century character. The mill dam is located a few feet upstream from the bridge. Although some alterations are present, they are predominantly non-intrusive in nature and the bridge retains its integrity of design.

Boundary Description and Justification: The bridge is individually distinguished, but it is also located in a potential historic district that appears to include resources on both side of the river. Thus both ends of the bridge are within the potential historic district. The bridge and its surroundings are evaluated as significant.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 2-span stone arch bridge was constructed in 1900. The upstream portion is ashlar with ringstones. It retains its lattice and floral boss railing. The bridge was widened in 1980 by a reinforced concrete addition of corresponding shape on the downstream side. The addition has a paneled concrete parapet. A concrete toe wall was added to the original pier. One of over 10 stone arches in the county, it has lost significance due to the alterations and is thus not a noteworthy example of the type.

SETTING / CONTEXT The bridge carries one lane of a rural road over the Musconetcong River, the boundary between Hunterdon and Warren counties. It is located in a wooded rural setting near open fields and pastures.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel half hip Pratt pony truss is pin connected. One abutment is fieldstone while the other is concrete. An unusual construction detail is cast iron connectors and bearing shoes similar to the bridge on Hamp Road (10WD120). Minor modifications made in 1977 include repairs to the vertical members and the addition of outriggers. This is a well-documented example of the Wrought Iron Bridge Co. of Ohio. Several other local spans by the company have the same cast connectors.

INFOR MATION

BIBLIOGRAPHY:

Hunterdon County Engineer's Office, Bridge card L-95-W.
Darnell, Victor C. A Directory of American Bridge-Building Companies, 1840-1900. Washington, D.C.: Society for Industrial Archeology, 1984.

PHYSICAL DESCRIPTION: The four-panel, pin-connected, half-hip Pratt pony truss bridge is traditionally composed. The top chord and inclined end posts are composed of shallow channels, toe out and a cover plate and closely spaced lacing, riveted to make a box member. The bottom chord is comprised of stamped, round- headed eyebars. Vertical members are angles with lattice bracing. Floor beams are hung from typical U-bolt hangers. One abutment is random fieldstone, while the second is concrete. Wingwalls have been repointed and repaired. An unusual detail is the cast-iron bearing shoe containing the roller nest. The cast bearing serves as the connection for the bottom chord and inclined end posts.

Alterations are minimal. Modern metal guide railings have been added to either side. A glue-laminated deck replaces a 1962 metal plank deck. Other alterations include welded repairs on vertical members and the addition of outriggers in 1977.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: One of over 20 Pratt half hip pony truss bridges in Hunterdon County, the well-preserved span is historically and technologically distinguished. It was fabricated by The Wrought Iron Bridge Company (WIBC) of Canton, Ohio in 1897. The company, noted for its prolificacy and technological accomplishments, was founded in 1864 by David Hammond, and it was incorporated in 1871. It operated as such until 1899 when it was absorbed by the American Bridge Company (Darnell, 48.). Nationally successful by marketing its designs through a network of regional salesmen, the company is well represented in New Jersey. What distinguishes this span are the bearing castings, a detail used on some of the company's bridges since at least the 1880s (criterion C). It is also found on 10WD120. The span thus documents the evolution of metal truss bridge design, but also the manner in which bridges were designed and marketed in the pre-American Bridge Company era.

Boundary Description and Justification: The bridge evaluated as individually distinguished. The boundary is limited to the substructure and the superstructure.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 6-panel riveted Pratt pony truss bridge has ashlar abutments, one of which has been widened with concrete. The bridge, designed by the county engineer is traditionally composed with the center-panels diagonals joined to a center gusset plate. The original pipe railing survives. Largely unaltered and although a relatively late example of a Pratt pony truss, the bridge is individually eligible for listing in the National Register under Criterion C.

SETTING / CONTEXT The bridge carries a lightly traveled rural road over a branch of the Neshanic River. It is located in a rural setting with nearby open fields and encroaching suburban housing development.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The skewed 5-panel 1936 Pratt pony truss bridge is of rolled section welded construction. It is supported on random ashlar abutments. An uncommon detail is the connecting of the center-panel diagonals to a mid-panel gusset plate. Alterations are minimal and include outriggers and guide rail railings. Although the structure is a representative example of the pony truss technology, it is not individually eligible for listing in the National Register of Historic Places, nor does it currently contribute to an identified historic district.

SETTING / CONTEXT The bridge carries one lane of a lightly traveled country road over Rockaway Creek. It is located in a wooded rural setting adjacent to a well-preserved 18th-century farmstead. The unspoiled setting contributes to the significance of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel pin-connected Pratt thru-truss bridge is supported on random ashlar abutments. The span is technologically significant because of its distinctive details including beveled bearing plates, paddle-shaped ends on the verticals, and bottom chord eyebars that pass under the pin connection. Portals are set on the top chords, which end in faceted stops. The fabricator is not documented, but the construction details are unusual and distinctive. It is technologically notable.

INFORMATION

BIBLIOGRAPHY:
Hunterdon County Engineer's Office, County Bridge card R20.
Hunterdon County Master Plan: Sites of Historic Interest, 1979.

PHYSICAL DESCRIPTION: The single-span Pratt thru-truss bridge is almost entirely original except for an asphalt filled corrugated metal deck. The bridge consists of what appears to be wrought iron I-beam stringers and floor beams hung with U-bolts from two truss lines. The trusses consist of inclined end posts and top chords built up from two channels and a cover plate with widely spaced battens. An unusual detail is that the ends of the top chords extend slightly beyond the portal diagonals and are finished with a decorative paling-ended end cap. The principal diagonals and bottom chord consists of round headed eyebars. The counters consist of rods with turnbuckles for adjustment. The verticals consist of channels with lacing. The original diagonal-pattern lattice railings are present along both truss lines. The bearing plate is an incline which results from the masonry plates having inclined web extensions. The rationale behind this bearing type is unclear. The bearings at both abutments are inclined back away from the span. There is no clear indication if one or both sets of bearings were intended to be the expansion bearings. The pins in the bearings have been welded in position.

The abutments consist of rubble stone masonry of poor quality, with U-type wingwalls. Concrete toe walls have been placed in front of both abutments to protect from scour.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE: The date of construction and fabricator of the well-preserved pin-connected Pratt thru truss bridge has not been documented in the County Engineer's records, but the span is mostly original, with few alterations, making it a good representative example of the important bridge type (criterion C). It is technologically distinguished by two unusual features not found on other thru truss bridges in the county. The top chord portal connection connotes extraordinary attention to detail. The inclined bearings appear to indicate a unique design philosophy. In addition to the preservation of the unusual construction details, the span enjoys integrity of setting in a wooded rural area adjacent to the Ten Eick-Weed farmstead, which includes a frame farmhouse with a stone wing, an English barn, and a smaller frame barn.

Boundary Description and Justification: The bridge is located adjacent to an 18th-century farmstead, but the history and significance of the two resources are separate and distinct. The bridge is evaluated as significant in its own right. Its boundary is the limits of the substructure and superstructure.

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 3-panel pin-connected Pratt half hip pony truss bridge is too long for the crossing, indicating that it may have been moved to this location. It bears on concrete abutments. Although it has been strengthened by a rolled girder from which the floor beams are suspended, the trusses themselves appear to be well preserved. The most unusual detail is the tapered-shape verticals which are composed of latticed back-to-back angles. The bridge is an altered example of a common county type.

SETTING / CONTEXT Located in downtown Trenton on the main east-west street, the 1843 stone arch bridge is not visible from the roadway. Assunpink Creek, the feature it crosses, has been diverted underground west of the bridge and it reemerges at the bridge. Open park land, created by urban renewal, is on both sides of the bridge which has been widened to 36'.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Historic District Status Unresolved.

CONSULT DOCUMENTS DOE 05/31/80

SUMMARY The well-proportioned random ashlar elliptical stone arch was built in 1843 to replace the 1822 stone arch bridge lost in a freshet. On the historic main road from New York to Philadelphia, a stone arch was first built here in 1774. The bridge was widened on the east side several times, but the west elevation survives with its handsome voussoirs and keystone. It is the oldest bridge in Trenton, and is of great historical value to the community.

SUMMARY Composed of rolled I-beams with shallow brick arch infill between the beams, the 1889 bridge was widened in 1926 with concrete-encased stringers. It is one of the few surviving brick jack arch bridges in the county, but the type is well represented within the county in spans of less than 20'. While the brick jack arch span is strong, the stone abutments are not and are braced. The brick arch added strength and stability to the I beams. A better, unaltered example of the type is 18E0104.

INFOR MATION

Bibliography:
Mercer County Engineers Office. Transfer File 422.4.
A.G. Lichtenstein & Associates. "Report of Finding of Historic Significance of Structure No. 442.4 Ewingville Road over Shabakunk Creek. 2/15/90.

Physical Description: The 24'-long span was built in two phases. The earliest is the northern portion composed of 7 rolled stringers spaced 4' apart with brick jack arch fill with a 6" rise. Tie rods through the I beams resist the lateral thrust of the brick arches. The jack arches are in good condition, The bridge was widened to the south in 1926 when five concrete encased stringers were installed. The original ashlar abutment is not well founded and is braced. Any historic railing has been lost. Modern beam guide rail is now in place.

Historical and Technological Significance: The Ewingville Road bridge is a documented example of a stringer and brick jack arch span. It was built in 1889 and widened with rolled steel I-beam stringers in 1926. Bridges with brick jack arches were built during a period between about 1885 and 1905. The detail is reportedly more common in Mercer County for culverts (spans of less than 20') than bridges. While considered a ferrous stringer bridge, the area between the webs was filled with longitudinal brick arches to assist in the load capacity of the span. The technique was copied from fireproof floor beam construction in buildings. A notable and early use of the barrel arch floor system was in the Custom House in Wheeling, West Virginia, begun in 1856 and completed in 1859. Interestingly, the I beams used in the building were among the first 7" beams rolled by the New Jersey Iron Company in Trenton. The use of brick in jack arches persisted until surpassed by reinforced concrete starting about 1905.

While the Ewingville Road bridge is a good example of its type, it has been altered with an addition to one side, and it is not as noteworthy as the one on River Road over Van Horn Brook in Somerset County (18E0104). That example is longer, has a higher clearance, and has not been widened.

SUMMARY Designed by county bridge engineer Harry Kersey, who did most of the 1920s bridges in the county, the encased stringer bridge with a paneled concrete parapet is a representative example of the bridge type that dominates Mercer county. Over 40 encased stringers were built in Mercer prior to WW II. This bridge is not historically or technologically distinguished. The parapet is somewhat deteriorated.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The handsome, well proportioned and well preserved arch bridge with paneled spandrels and corresponding parapet was designed by Morris Goodkind (1888-1968), State Bridge Engineer from 1925 until 1955. Goodkind also did consulting and was one of the most influential engineers in the state. Concrete arch bridges are not common in Mercer County, where the County Engineer favored concrete-encased stringers. The Carter Road bridge is eligible under the theme of Goodkind bridges.

INFOR MATION

Bibliography:
Mercer County Engineer. Transfer file: 543.7.
The Daily Home News (New Brunswick, NJ), September 7, 1968, p. 1. Lichtenstein, Abba G. Interview with m. McCahon, 4 January 1991.

Physical Description: The well-proportioned elliptical earth-filled reinforced concrete deck arch bridge has solid paneled spandrels with a brush hammered finish. The concrete parapets are also finished with flat panels. The bridge stands in a good state of preservation and is an excellent example of its structural type.

Historical and Technological Significance: The well-proportioned reinforced concrete arch bridge was designed in 1921 by Morris Goodkind (1888-1968) who worked briefly for Mercer County before going on to a distinguished career as chief bridge engineer with the New Jersey State Highway Department from 1925 until 1955 when he went into private practice as a principal of the firm Goodkind and ODea. He was Engineer of Bridges during one of the periods of greatest road expansion that the state has ever experienced. Goodkind started with NJDOT's bridge division in 1922, and he was largely responsible for the used of concrete-encased steel stringer bridges throughout the state as he recognized the benefit of encasing the concrete to protect it. Additionally, he is honored by his peers as a leader in long-lasting bridge design by setting state standards that exceeded those of AASHO, like an 8" concrete bridge deck depth and 1/1200 maximum span deflection. The body of his design work chronicles the transition from the truss era to the use of modern materials, especially concrete, and the role of the professional engineer in the development of both politically controlled policy and transportation networks. In addition to influencing the choice of technologies, Goodkind was responsible for the aesthetics of bridges in the state for over three and a half decades.

The 1921 Carter Road arch bridge is an early example of his work. One of two bridges in the county designed by Goodkind, it is distinguished by its handsome proportions and nearly complete state of preservation. Concrete arch bridges are not common in Mercer County.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The 4-panel pin-connected Pratt half hip pony truss, moved to this location in 1930, is one of the two examples in Mercer County. Two verticals on the south end of upstream side are replacements, but the others are composed of an unusual rolled T section, a detailed unique to Wrought Iron Bridge Co. spans. The bridge is well preserved and is supported at one end on ashlar abutments from the previous span. The bridge is eligible because it is a documented early example of a WIBC span.

INFOR MATION

Bibliography:
Mercer County Engineer's Office: Transfer File 672.7.
Waddell, J.A.L. Bridge Engineering. 1925.

PHYSICAL DESCRIPTION The 15'-wide 4-panel pin-connected half hip Pratt pony truss with a plank deck survives with few modifications to its original design. Its top cord, inclined end posts are composed of plates and channels riveted to make a box member. The most distinctive feature of the bridge are the rolled or cast "beaded Tee" sections used for the original laced verticals. The heavier angle verticals with lattice and batten plates at the southwest corner appear to be not recent replacements that are consistent in style and type with the original design of the bridge. The diagonals are bars with loop forged eyes and sleeve nuts in the middle panels where the load is the greatest. Counters are lighter rods with loop forged eyes. A gusset plate riveted to the bottom on the verticals serves as the connection at the pin. The rolled section floor beams, which appear to the originals, are connected by typical U-bolts hangers. Strengthening knee braces, or outriggers, are bolted with regular bolts to the floor beam but riveted at their upper connection. A steel curb and original/early pipe railing provide impact protection for the truss on the downstream side, but modern beam guide rail has been welded to the road side on the upstream truss. The modern guide rail is the most drastic modification to the span.

The abutment for the previous span (also a pony truss) was modified to accept this structure which was moved to the site in 1930. The ashlar west abutment was not altered, but a new reinforced concrete abutment was added to the existing ashlar abutment on the east side because this structure is shorter than the earlier span.

HISTORICAL AND TECHNOLOGICAL SIGNIFICANCE The date of construction of the well-preserved Pratt half hip pony truss is not documented, it is known to have been designed and fabricated by the Wrought Iron Bridge Company of Canton, Ohio prior to 1885. Originally erected over Jacobs Creek on the Washington Crossing-Pennington Road in Hopewell Township (#214.4), it was dismantled truss by truss, and moved to Groveville-Allentown Road in 1930 (Mercer County Engineer's Transfer File 672.7). Reusing of pony truss bridges was apparently a common practice in Mercer County. Other documented examples of a similar relocation is Iron Bridge Road in Hamilton Township. Despite the relocation, the pin-connected truss survives in a remarkably complete state of preservation with no readily visible welded repairs. Outriggers or knee braces have been added at the panel points to brace the top chord against buckling outward, a modification frequently made to pony trusses.

The most distinctive feature of the bridge are the seldom-seen rolled or cast "beaded Tee" sections employed in the vertical members. As explained in its 1885 catalog, the "beaded Tee" was a Wrought Iron Bridge Company patented detail designed to be used in "the wide Lattice Post ... to give perfect lateral bracing to the girders, and is much neater in appearance than the cross or side braces formerly used for this purpose." The same patented section shape is used on the Devereux Road bridge over the East Branch of Brandywine Creek in Chester County Pennsylvania (Chester County #138). That bridge was fabricated by the Wrought Iron Bridge Company and has a patent date of 1877, according to Chester County records.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is limited to the superstructure. The substructure is not original to the truss lines as the span was moved to this location in 1930.

SETTING / CONTEXT The bridge is located on a 2-lane road in the agricultural southeast corner of the county near the Burlington County line. A NJ Turnpike overpass is located just north of bridge, and a small roadside park is adjacent to the southwest side. The setting is undistinguished.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 06/21/94, Letter 03/12/01.

SUMMARY The 4-panel riveted Warren with verticals pony truss bridge with original knee braces was fabricated in 1915. It is supported on concrete reinforced ashlar abutments that have been undermined. While the trusses themselves are in reasonably complete condition with only minor welded repairs, the bottom chord and bearings have been encased in concrete, and a concrete deck has been added. The bridge represents a type which was designed in the late nineteenth and early twentieth centuries for the light vehicular traffic characteristic of rural America at the time. Despite an alteration which affects the functioning of the bottom chord, the bridge retains integrity of its original materials, construction and configuration, and is individually eligible for listing in the National Register under Criterion C.

SETTING / CONTEXT The bridge is an element in dam/bridge structure located in the center of the historic mill village of Grovers Mill. The 19th-century mill and races are located on the northwest side of the bridge while the large mill pond is to the east. The bridge crosses the overflow channel. 19th- and early 20th-century houses and barns dominate the surroundings area which appears to have National Register historic district potential.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Grovers Mill Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The encased stringer bridge and dam are the most modern elements in Grovers Mill, a well-preserved crossroads settlement clustered around the 19th-century Grover mill and pond. The mill was powered by water until the early 1950s. The 1931 bridge/dam was built within the period of significance of the mill. The bridge with a paneled concrete parapet is a good unaltered example of a structural type commonly used in prior to WW II. It and its historic setting are well preserved. It is eligible listing in the National Register of Historic Places as a contributing element of the Grovers Mill Historic District, eligible under Criteria A and C.

INFOR MATION

Bibliography:
Woodward & Hageman. Histories of Burlington and Mercer Counties. 1888. Everts & Peck. Dennison, William.
Phone Conversation with Mary E. McCahon. 23 August 1991. (919-799-4417).
Trenton Public Library. Trentoniana Collection. Vertical File: Radio.

Physical Description: The 24'-long concrete-encased rolled stringer bridge with a concrete paneled parapet is one element in a larger reinforced concrete dam and spillway adjacent to the intersection of Clarksville and Cranbury roads in the rural northeast portion of the county. The concrete dam has a buttressed hexagonal spillway to a concrete floor. The flow of the stream is further channeled by wing walls. The head race for the turbine-powered mill is at the northeast corner of the downstream side. The dam has no separate overflow, a feature not needed with the hexagonal shape of the spillway, which also serves as the overflow. The approach on the south side of the bridge is lined with the original pipe and concrete post railing.

Historical and Technological Significance: The 1931 bridge and dam were designed by County Bridge Engineer Harry Kersey. Kersey designed nearly all the bridges built in the county during the 1920s and 1930s, and his preference was the concrete-encased rolled steel stringer span, a straightforward structure noted for its economy and durability. He also frequently used paneled concrete parapet.

Grovers Mill is a crossroads community that developed around the grist mill on Bear Creek. The earliest mill dates to the Revolution, and the present flour mill was acquired by John Grover in 1860. When William Dennison's father purchased the mill about 1930, it was powered by a water-driven turbine (still in place). William Dennison took over operation of the mill after his father's death in 1945, and he gradually converted operation of the milling equipment to electricity. The water-powered turbine was taken out of service in the early 1950s. Thus the dam and bridge were an integral part of the water-powered operation of the historic mill during its period of significance. William Dennison used the sluice gate in the dam/bridge structure consistently until the mill was converted to electricity. The head race, which goes under Clarksville Road, is still in place. While the mill itself has been converted to residential/commercial use, much of the historic fabric, including the races, some shafting, and the historic appearance of the building itself survive making it one of the important elements in any potential historic district.

Grovers Mill gained national notoriety in 1938 when writer Howard Koch named it as the landing site of the Martians in the Orson Wells Halloween eve production of Koch's adaptation of "War of the Worlds."

Boundary Description and Justification: The bridge crosses the overflow of the mill pond associated with a potentially eligible mill. The mill and pond are also located in a potential historic district. The bridge is evaluated as contributing to that historic district. Thus the bridge and its surroundings appear to be significant.

SETTING / CONTEXT Located in the borough of Hightstown immediately west of Peddie School, a private prep school, the bridge carries a 2-lane city street over Pedddie Lake, a former mill pond. Open land is to the east side of the bridge. The bridge contributes to the 19th-century character of the town.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The well-preserved 2-span bridge is a rare example of a double-intersection Warren truss with hangers. It was fabricated by the important New Jersey Steel & Iron Co. of Trenton and is a late but significant example of the firm's bridge work. Since only a masonry plan survives, the span may have been a proprietary design. It is one of most significant thru trusses in the county because of its type, maker, and state of preservation. The steel grate deck was installed in 1969.

INFOR MATION

Bibliography:
Geiger, Carl. The Peddie School First Century.
Mercer County Engineers Office. Transfer File & Plans #863.4.

Physical Description: The well-preserved 2-span thru truss bridge on coursed ashlar abutments and mid-stream pier is an unusual and possibly unique double intersection Warren with floor beam hangers. The panel points and hangers carry built-up floor beams which appears to be original. The present steel deck and stringers were installed in 1969. The inclined end posts and top chord are composed of channels and plates while the diagonals are toe-out angles joined by battens. The tension members have narrower battens and pass through the wider-spaced compression members. The lattice portal brace is topped with cresting at the outside panels, and the roller bearing of each span is also located at the abutment end. The pipe railing which passes through the compression members is original. With the exception of the steel open grid deck, the bridge is in remarkably complete condition with no visible major welded repairs. The grid does not detract from the integrity of the bridge.

Historical and Technological Significance: The 2-span thru truss built in 1896 is a nearly complete example of the uncommon double-intersection Warren with floor beam hangers. It was fabricated and possibly designed by the New Jersey Steel and Iron Company of Trenton, one of the most important mills in the country prior to its absorption into the Carnegie's American Bridge Company in 1901. The company was established as the Trenton Iron Company in 1846 when Peter Hewitt received a $180,000. contract for rolled iron rail from the Camden & Amboy Railroad. In 1854 the company produced the first rolled 7" I-beams. The rolled beams were to revolutionize building construction. Trenton Iron & Steel Co. produced all kinds of structural steel, including shaped steel for many New York City skyscrapers, elevated street railways in New York and Brooklyn, and even Civil War-era gun barrels. Mercer County records indicate that many New Jersey Steel and Iron Company bridges once stood in the county. The non-extant mid-1880s viaducts over North Olden and Southard Streets in Trenton were their work as is the extant 1888 Jackson Street Pratt truss in Trenton

The well-preserved East Ward Avenue bridge survives as one of the best albeit late examples of a New Jersey Steel and Iron Company bridge in the region. It is an unusual example of a double intersection Warren with floor beam hangers. Technologically it represents one of the many variations on the traditionally used trusses that were promoted and marketed during the last quarter of the 19th century. Prior to the consolidation of smaller bridge fabricating companies into the American Bridge Company conglomerate in 1901, the independent fabricators both designed and fabricated the trusses they marketed.

The bridge spans Peddie Lake, a long narrow mill pond created in the 18th century by damming Rocky Creek, a tributary of the Millstone River. The pond's water powered grain mills through the 19th century. The lake is now named for the private school located on its western shore. Founded in 1864 as the New Jersey Classical and Scientific Institute by the state's Baptists, the name of the preparatory school was changed in 1872 to honor its chief benefactor. The bridge carries a local street and serves as a more direct route to the northeast section of town, a predominantly 19th century community.

Boundary Description and Justification: The bridge does not appear to be located in or contiguous to a potential historic district. It is not historically related to the Peddie School that is located on the west side of the span. Therefore, the significant boundary is limited to the span itself and does not include surrounding property.

SUMMARY The bridge is a combination 1- and 2-span thru girder bridge on concrete abutments and pier. The design and structural type were mandated by the skew angle of the crossing, and the floor beams are perpendicular to the girders, but not the abutment of the west span. The cantilevered sidewalk on the west span was removed to reduce the dead load, according to the county. It survives on the east span as does the concrete balustrade. While unusual, the bridge is not technologically significant.

SETTING / CONTEXT The bridge crosses a small stream and is located on a heavily used road in a rural, sparsely developed portion of the county. The setting is undistinguished.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The bridge is composed of steel stringers with 6"-deep concrete jack arch strengthening. It was widened in 1941 from its original 18' width to 30' by the addition of 6' to each side. A successor to brick jack arch technology which was used from about 1885 until 1910, concrete jack arches are not a common structural type. This one, however, is not a well preserved example owing to the 1941 addition. It is scheduled to be replaced by the county in 1991-92.

SETTING / CONTEXT The bridge originally crossed the tracks and yard of the Camden & Amboy Railroad (later PA RR) and the Delaware & Raritan Canal. The canal has been redeveloped as the Trenton Freeway (US 1). The area is industrial with most of the development dating to the 20th century. There is no National Register historic district potential. Neither the bridge nor the surroundings have integrity of setting or design.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Listed. D&R Canal. 05/11/1973. Noncontributing.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY Designed by J.A.L. Waddell as a thru girder viaduct with a vertical lift span, the viaduct was drastically altered in 1943 when the towers and operating mechanism of the lift span on the north end were removed and the span was fixed. It is supported on concrete piers, encased steel bents, and concrete abutments that incorporate the ashlar abutments from the earlier pinned thru truss. The viaduct is similar to N. Olden Ave. (1100050) which was found not eligible in 8/20/90 SHPO Finding.

INFORMATION

Bibliography:
Mercer County Engineers Office; Transfer File #120.2.
Dictionary of American Biography. Vol. XI, 1958. Charles Scribner's Sons.

Physical Description: The 6-span, 360'-long thru girder viaduct was originally constructed with a vertical lift span at the north end. The riveted built-up girders with knee braces rest on an ashlar abutment from an earlier span on the north end while the southern abutment is reinforced concrete. There are also intermediate concrete columns. Portions of the brownstone ashlar wing wall and iron lattice railing from the ca. 1885 bridge survive on the south side. Each end of the outermost girders are protected by a concrete pedestal with a commemorative plaque. The cantilevered sidewalk has a chain link fence for a pedestrian protective barrier.

The vertical lift span was removed in 1943. Evidence of its existence can be found in the span division and reinforcing of the shoes at the former lift span. The bridge has functioned as a simple multi-span thru girder since 1943, and as such it is a representative example of its type. The thru girder with floor beams was favored for longer spans for its economy and rigidity. Because it is in an industrial rather than a residential portion of the city, it was acceptable to have an exposed, unadorned girder. The floor beams are encased, but the encasing is in poor condition.

Historical and Technological Significance: The present appearance and setting of the multi-span steel thru girder bridge does not reflect the original design or context of the bridge. Designed by the firm established by the noted engineer and author John Alexander Low Waddell of New York, the bridge was originally a vertical lift built in 1921-22 over the former main line of the Camden & Amboy Railroad and the Delaware and Raritan Canal. Neither the water-filled portion of the canal at this location nor the movable span survive. The North Olden Avenue viaduct, the viaduct immediately north of this one, was a nearly identical structure, also designed by the Waddell firm.

The viaduct replaced a 4-span pin-connected Pratt thru truss with a bobtail swing over the canal. The new bridge reused the north abutment from the ca. 1885 truss, and some of the lattice railing and brownstone ashlar wing walls also survive. The lift span, which existed for only twenty years, was operated by a train of gearing driving four spiral-grooved drums located at the center of the span. The drums were fastened by four wire ropes that passed under deflecting sheaves under the sidewalks at the four corners of the lift span, thence up to the tops of the towers, where they were fastened. Four similar ropes passed over the deflecting sheaves, then downward to fastenings on the towers. By rotating the drums in one direction, the uphaul ropes were wound on the drums causing the span to rise. The bridge was operated by an electric motor. When the canal was closed to navigation and turned over to the state by the Pennsylvania Railroad in the early 1940s, the need for a movable span over the waterway was unnecessary. The bearing points of the lift span were reinforced, and in 1943 the towers were removed by Bugbee & Company, a Trenton firm, with the material donated to the federal Metal Reserve Company for the nation's scrap pile.

J.A.L. Waddell (1854-1938) was one of the best-known bridge engineers of his day. His writings, which promoted the importance of the consulting engineer, were as much responsible for that fame as his bridges. He is credited with developing the modern vertical lift bridge. Waddell moved his practice from Kansas City to New York in 1920, where he practiced alone until taking his long-time associate Shortridge Hardesty into partnership in 1927. Mr. Hardesty was the supervising engineer on this project.

The history of the bridge and its predecessor are well documented in the Mercer County Engineers Office, but both the structure and its setting have been drastically altered and thus no longer appear as they did during their period of significance. Although the bridge was designed by an important engineering firm, it is not a noteworthy or innovative example of their work. Waddell had been designing vertical lift bridges since the Halsted Street bridge in Chicago in 1893. Even more significantly, the bridge lost its integrity of original design when the lifting mechanism was removed in 1943. Additionally the canal was diverted and its right-of-way redeveloped as the 4-lane limited access Trenton Freeway beginning in 1951, erasing the original/historic setting of the bridge.

SETTING / CONTEXT The bridge carries a city street over Assunpink Creek in an urban, mid-19th century mixed use neighborhood in downtown Trenton. The surroundings are dominated by row houses that are being restored. Some modern, incompatible redevelopment has occurred to the north and east of the bridge. The span contributes greatly to the historic character of area.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Listed. Mill Hill Historic District. 12/12/1977. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The handsome 2-span rubble-coursed stone arch bridge with its original cast iron balustrade, the only known example of its type in the area, was designed by Trenton architect Henry E. Finch. He also did the 1869 S. Clinton St. stone arch bridge. The well-preserved bridge with voussoirs contributes to the architectural significance of the Mill Hill Historic District. The 1977 NR nomination does not include an inventory, but the bridge is mentioned in the text as a contributing resource. It is also individually significant based on its type, completeness, and association with architect Finch. The bridge is individually eligible for listing in the National Register under Criterion C and is a contributing element to the Mill Hill Historic District.

SETTING / CONTEXT The bridge over channeled Assunpink Creek in downtown Trenton is next to the former Pennsylvania RR passenger station. The station was moved to this location in the early 1860s. The south end of the stone bridge serves as the abutment for the contiguous 1892 truss bridge that crosses the tracks immediately east of the channeled creek. Much of the area surrounding the bridge has been cleared or redeveloped.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY One of several well-preserved multi-span stone arches in downtown Trenton, the 1869 rubble ashlar double barrel arch bridge with high spandrels was designed by local architect Henry Finch. The beam guard rail and pipe railing are modern as is the icebreaker. The arch bridge serves the abutment of an 1892 thru truss span, and the pair provide a rare tandem example of 19th-century solutions to engineering and transportation considerations. The crossing is one of the most historic in Trenton.

INFOR MATION

Bibliography:
Mercer County Engineers Office. Transfer File # 140.6.
Trenton Public Library. Trentoniana Collection: Vertical File; Architecture.

Physical Description: The well-proportioned 2-span random ashlar brownstone stone arch bridge with a deep spandrel has uniform ring stones, a keystone, and cap stones. Each arch has a 20' rise and is 36' wide. The structure continues into a curved wing wall on the north side. The bridge is the northern portion of a two-bridge arrangement that carries the local street over Assunpink Creek and the main line of the Camden & Amboy Railroad (Pennsylvania Railroad after 1871) which parallels the creek. The railroad right-of-way was established in 1862 as part of the line's realignment and double tracking through Trenton. Any original railing has been replaced by 20th-century pipe railing and modern steel guide rail. A concrete bullnose cutwater has been added to the upstream side, and a concrete wall directs the upstream channel of Assunpink Creek. The bridge is well preserved.

Historical and Technological Significance: The handsome stone arch bridge, designed by notable local architect Henry E. Finch, is part of the most significant pair of bridges in the area. Serving as the seat for the 1891 pin-connected double intersection Pratt truss that crosses four active lines of track at the west end of the main Trenton station, the stone arch is an integral part of the engineering solution to separate rail and local vehicular traffic as well as cross a water feature. The integrated pair of bridges represent two distinct epochs of 19th-century bridge technology, and that juxtaposition is rare if not unique.

The arch was designed by Henry E. Finch, a prominent Trenton architect who designed approximately 2,000 buildings in the city (Trenton Public Library. Trentoniana Collection. Architects Vertical File). He came to Trenton in 1855 and served his apprenticeship with architect Chauncey Graham, his first partner. In 1863 Mr. Finch established his own practice and went on to become the most prominent and prolific local architect. He designed residences, many in brownstone, the material he specified for his arch bridges, and factories. In addition to the South Clinton Street arch also designed the E. State Street (1100053) and Montgomery Street (1100051) stone arch bridges. Finch had retired from practice by 1923.

The stone arch bridge is one of four of its type from the 19th century that remain in downtown Trenton. No original plans for the bridge survive, but A. Carlile is listed in county records as the contractor.

NAME & FEATURE INTERSECTED NORTH OLDEN AVENUE OVER ASSUNPINK CREEK **FACILITY** NORTH OLDEN AVENUE

TOWNSHIP TRENTON CITY

TYPE STRINGER **DESIGN** ENCASED **MATERIAL** Steel

 # SPANS 1 **LENGTH** 76 ft **WIDTH** 36 ft

CONSTRUCTION DT 1937 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT H. KERSEY, CO BRIDGE ENGINEER **BUILDER** TRENTON CONCRETE CO.

SETTING / CONTEXT The bridge is located in the industrialized section of Trenton once dominated by rubber, textile, and pottery operations and the Pennsylvania Railroad's main line to New York. Because of deterioration and urban renewal, the area does not have historic district potential.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The skewed encased stringer bridge erected in 1937 is a representative example of the most common pre-WW II bridge type in the county. Designed by county bridge engineer Harry Kersey, it is one of over forty stringer bridges in the county. The bridge is not historically or technologically distinguished.

CONSTRUCTION DT 1922 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT MORRIS GOODKIND **BUILDER** F. B. JOHNSON CO. TRENTON

SETTING / CONTEXT The bridge is located in the main industrial district in Trenton next to the former Empire Rubber Company plant. It crosses Assunpink Creek, the historic source of power in the area. The bridge carries a local 2-lane collector street.

1995 SURVEY RECOMMENDATION Not Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The partially encased thru girder bridge with floor beams and concrete end posts was designed by Morris Goodkind who at the time was the Engineer of Bridges with the State Highway Department. The girders are not technologically innovative, and the cantilevered sidewalks have a traditional concrete balustrade. The bridge is adjacent to the former Empire Rubber Co. plant, which may NR-eligible, but the bridge does not appear to be historically associated with the facility.

TOWNSHIP TRENTON CITY

TYPE STRINGER **DESIGN** ENCASED **MATERIAL** Steel

 # SPANS 2 **LENGTH** 84 ft **WIDTH** 40.3 ft

CONSTRUCTION DT 1930 **ALTERATION DT** **SOURCE** PLAQUE

DESIGNER/PATENT H. KERSEY, CO BRIDGE ENGINEER **BUILDER** GRANT CONST. CO.

SETTING / CONTEXT The bridge is located at the intersection of Wall, E. State and Chestnut streets in downtown Trenton, and it crosses Assunpink Creek, the major stream through Trenton. H.D. Lee Co. is on the west side of the bridge. In addition to the overall manufacturer, the neighborhood features vernacular workers housing. Wall Street was not extended across the creek until ca. 1920.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Not Individually Eligible. Potential Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The skewed 2-span encased stringer bridge on concrete abutments and piers is significant for its historical association with the adjacent H.H. Lee Co. factory. The bridge with balustrade enclosed cantilevered sidewalks was built to provide better access to the factory. A well preserved example of its structural type, the bridge is a contributing resource to the potential H.D. Lee historic district. The Lee factory is one of the finest local examples of the Moderne style of architecture. The bridge is not individually eligible for listing in the National Register of Historic Places, but may be a contributing element to a local residential / manufacturing historic district which appears to be potentially eligible under Criteria A and C.

INFOR MATION

Bibliography:
Trenton Times. "Lee Moving..." 3/28/66.
Sanborn Insurance Maps. 1885-1927.

Physical Description: The skewed (41 degree) 2-span simply supported encased steel stringer bridge has reinforced concrete abutments and central pier with an upstream cutwater. It is typical period construction and style. The cantilevered sidewalk is finished with a reinforced concrete balustrade that is severely deteriorated.

Historical and Technological Significance: Located over Assunpink Creek at the intersection of E. State Street, the bridge is important for its associative significance with the H.D. Lee factory rather than its technological importance. Representing typical period technology, the bridge was constructed as the second span to carry Wall Street, a residential thoroughfare, over Assunpink Creek and to provide vehicular access to the freight entrance of the Lee factory. East State Street was an unimproved road until the 1860s. In 1920 H. D. Lee secured the previously undeveloped parcel on the corner of E. State Street and Assunpink Creek for its Trenton plant. The overall and work clothing manufacturer started in Kansas City in 1912 and came to Trenton in 1917. In 1916 it became the first clothing maker to start carrying a union label and consequently identified its popular coverall as "unionalls." The 6-story reinforced concrete frame plant was built in 1920 and was used until 1967. It survives in a remarkably complete state of preservation and ranks as one of the finest examples of the Moderne style in the area. Lee, employing as many as 600 workers at its peak, was an important Trenton industry. The well-preserved facility, which symbolizes both Lee's corporate history and the industrial development and prosperity of Trenton, appears to be an eligible resource. The bridge was constructed to accommodate the historic use of the building, and thus is also eligible as part of the Lee Historic District.

Boundary Description and Justification: The bridge is not individually significant. Its importance is for its association with the potential National Register-eligible building at its northwest quadrant. The other quadrants of the bridge are not significant. Thus the bridge and the northwest quadrant are evaluated as significant. If the building is determined to be a not eligible resource, then the bridge is likewise.

DESIGNER/PATENT KING IRON BRIDGE CO. **BUILDER** UNKNOWN

SETTING / CONTEXT The bridge in a wooded setting is located in a well-maintained low-density suburban residential portion of the county and it carries a busy county road over a small stream. The historic name of the road is derived from a 19th-century tavern located well north of the bridge.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible.

CONSULT DOCUMENTS SHPO Finding 4/30/91

SUMMARY The 4-panel half hip pin-connected Pratt thru truss bridge supported on ashalr abutments was designed and fabricated by the King Iron Bridge and Manufacturing Company of Cleveland in 1882. It is the oldest thru truss bridge in the county. The bridge is nearly identical to, although 27' (one panel) shorter than, the 1885 King Iron Bridge Co. span on Mine Road (1100072), which is also eligible. The bridge is well preserved, with welded repairs limited to the lower portions of some verticals.

INFOR MATION

Bibliography:
Simmons, David A. "Bridge Building on a National Scale: The King Iron Bridge and Manufacturing Company." The Journal of the Society for Industrial Archeology. Vol. 15, No. 2, 1989. Mercer County Engineers Office.

Physical Description: The six panel half-hip Pratt pin-connected thru truss with a wood deck rests on an ashlar abutments. The inclined end posts and upper chords are built-up box members composed of shallow channels with a face plate. 3" by 2" angles are used for the laced verticals. Diagonals and counters are both rods fitted with turnbuckles for tuning the bridge, and the bottom chords are made up of square eyebars with drop forged eyes. The originality of the rolled I beam floor beams is not known, but a 1972 inspection report states that they are wrought iron. The lateral bracing is connected to brackets riveted to each beam. The plain portal struts have diagonal corner braces and each strut carries a King Iron Bridge and Manufacturing Co. plaque. A few welded repairs to the verticals at the panel points are visible, but otherwise the bridge is very well preserved. Some verticals have also been bent from impact damage.

Historical and Technological Significance: The well-preserved 75'-long pin-connected thru truss fabricated by the King Iron Bridge and Manufacturing Company of Cleveland, Ohio was erected in 1882, according to its plaque, and is one of two King thru trusses from the 1880s in Mercer County. The bridge is an excellent example of a standardized pin-connected Pratt design, the most common late-19th century bridge type. On a road named for an early-19th century tavern located to the north, the Bear Tavern Road Bridge, as well as its counterpart on Mine Road (1100072), is a regionally important survivor of a historic bridge type that has become rare.

The King Iron Bridge and Manufacturing Company was established by Zenas King in Cleveland about 1860. Learning the bridge selling business in the 1850s as a salesman representing the Moseley Bridge Company (a patented tubular bowstring), King patented his own tubular bowsting bridge that was to be the company's chief product through the 1870s, and he successfully marketed it nationally through a network of regional representatives. He published catalogues in 1875 and 1884 as well as annual reports, and, as the market moved away from the light bowstring truss about 1880, he diversified his product line to include what was becoming standard thru and pony truss bridges. The King company was one of the largest and most prolific bridge fabricating firms in the country yet only less than half a dozen documented examples of the firm's work survive in New Jersey. While the company remained an active, viable concern for about a decade after the founder's death in 1892, it was not a regional force this century.

The King Iron Bridge and Manufacturing Company, known as the King Bridge Company after 1892, represents, in addition to period engineering and technology, the manner in which iron and early steel bridges were marketed in this country. The fabricator served as both engineer and builder. That practice was to disappear with the rise of the consulting engineer and the professionally trained county engineer in the early years of this century.

Boundary Description and Justification: The bridge is evaluated as individually significant. The boundary is thus limited to the span itself.

CONSULT DOCUMENTS SHPO Letter 6/30/95

SUMMARY The steel stringer bridge with a modern beam guardrail is of no technological or historical significance. Initially composed of 4 rolled I beams, it has been widened by a bracketed addition to the east side. The high rusticated ashlar abutment from a previous span has been reused. The stringer span is one of over 40 built in Mercer County prior to WW II.

SETTING / CONTEXT The bridge is located over Assunpink Creek on a busy 2-lane road that is an exit from US 1. The historic Whitehead rubber factory is on the south side of the bridge while the mill pond is to its east. The bridge is an integral part of the industrial complex.

1995 SURVEY RECOMMENDATION Eligible **HISTORIC BRIDGE MANAGEMENT PLAN (EVALUATED** No

CONSULT STATUS Individually Eligible. Potential Whitehead Brothers Historic District. Contributing.

CONSULT DOCUMENTS SHPO Letter 03/12/01

SUMMARY The 5 short span encased stringer bridge was built in 1907 and then enlarged in 1938 because of the Whitehead Brothers Rubber Company plant. A good, unaltered example of its structural type, the bridge is individually eligible for listing in the National Register and is a contributing resource to the potential Whitehead Bros. Rubber Co. NR historic district. The bridge was enlarged to meet the needs of the company, and its significance is based on its historical association with the Whitehead Bros. plant.

INFOR MATION

Bibliography:
Mercer County Engineers Office. Transfer File #6-540.2.
Trenton Public Library. Trentoniana Collection: Vertical File: Rubber Industry.

Physical Description: The 84'-long five-span encased stringer bridge with cantilevered sidewalks and a concrete balustrade was built in two sections. In 1907 a 5-span pony truss was replaced by encased rolled stingers supported by the existing masonry abutments and piers that were capped with concrete. That span, 18'-7" wide, was deemed too narrow and was widened to 30' plus two sidewalks in 1938. Encased stringers were again used. The reinforced concrete balustrade is from the 1938 widening, and its style with bold paneled posts is typical of the period. The bridge is well preserved.

Historical and Technological Significance: The 1907 bridge is adjacent to the former Whitehead Brothers Rubber Company, a well-preserved 19th- and 20th-century industrial complex that appears to meet the criteria for inclusion in the National Register of Historic Places. The bridge was widened in 1938 to provide better access to the Whitehead mill and to provide adequate sidewalks for the workers. The size and appearance of the bridge are directly related to the plant which, beginning in 1870, produced rubber goods including hoses, valves, springs, belting, packing, and bicycle tires. The factory was initially located in a converted woolen mill that the Whitehead brothers had operated during the Civil War. Between 1937 and 1955 the plant was acquired by another rubber product manufacturer, the Goodall Company, which closed the facility in 1990. The complex, of which the bridge is a contributing resource, is one of the best preserved rubber factories in the city. Rubber products ranked second only to pottery as a leading industry in Trenton. The Whitehead Brothers were among the earliest manufacturers in the city.

Boundary Description and Justification: The bridge is located in potential historic district. It crosses the stream that was dammed to form a mill pond. The water originally powered the 1870 factory that is the nucleus of the present industrial complex. The mill pond would be a contributing resource to the potential historic district, as would the bridge that was originally built and then improved to meet the needs of the eligible factory. The bridge and the features on both sides of it are evaluated as significant.
